The biggest obstacle in this area of research is the *criterion problem*. There is no widely accepted and universally applicable criterion of creative performance with which to give divergent thinking tests (or any other test of creativity) a fair evaluation. Divergent thinking tests have demonstrated only moderate, and sometimes disappointing, predictive validity. When fluency, originality, and flexibility are all taken into account, predictive validity coefficients have reached 0.55. There is also impressive longitudinal data with predictive validity coefficients of approximately 0.30, with certain criteria—over a 50 year interval. Some of the newer research uses a criterion called the RIBS (*Runco Ideational Behavior Scale*), which was designed specifically for the testing of divergent thinking and focuses entirely on ideas. When it is used both the predictor (the divergent thinking test) and the criterion (the RIBS) focus on ideas, and not surprisingly, the correlation is quite reasonable.

Divergent Thinking and Idea Evaluation

Divergent thinking tests assess how well people generate ideas. As mentioned briefly above, the generation of ideas is, however, only one part of creative thinking. It is very important to be able to judge ideas, as well as generate them. Further, for creative thinking it is also necessary to judge ideas specifically for originality. Some kind of critical thinking may allow an individual to recognize whether or not an idea will solve a problem, but this is a very different thing from recognizing originality. There is, then, a difference between valuation (seeing the originality of an idea) and evaluation (seeing the effectiveness of an idea). A series of studies suggests that both of these are correlated with, but far from identical with, traditional divergent thinking indices. Hence someone can do one but perhaps not the other. Someone can generate ideas but not judge them accurately, or vice versa. There is also a difference between inter- and intrapersonal judgmental accuracy, but disappointingly, in both cases the accuracy is below 50%. In other words, original ideas are recognized as such less than half of the time! These findings of only moderate judgmental accuracy have been used to support the theory that creative thinking is more blind (or random, to use the Darwinian label) than guided.

Conclusions

Divergent thinking tests are grounded in sound theory. In particular, both associative theory and Guilford's own SOI model support the use of divergent thinking tests. Their use in research has generated many interesting results. Divergent thinking has been used in studies of the fourth grade slump, for example, and in investigations of the relationship of creativity with suicide ideation. Much of this research is reviewed in other entries in this encyclopedia. The corpus of research on divergent thinking is advantageous in the sense that the strengths and weaknesses of these tests are well known. Interpretations of test results are fairly straightforward, given the large literature on divergent thinking. Another strength is the practicality of the tests. They can be used in various settings (e.g., educational, clinical, and organizational) and can be used as exercises or assessments. As noted above, when used as assessments, they are best viewed as estimates of the potential for creative thinking and problem solving.

General Introduction

Imagine sitting in your favorite restaurant—you come here often so you know the place well. In the restaurant, business is going as usual. You brought your daughters, who are sitting at the table playing with a toy car. When the waiter comes back with the bottle of water you ordered, he gets distracted, and puts the bottle on the edge of the table. At the same time, the toy car slips out of your daughters's hands, slides towards the bottle, and knocks it over. Against all expectations, the bottle does not fall on the ground, but slowly moves towards the ceiling. You are stunned. You did not expect this to happen, nor did you think this ever could happen.

In an experimental study conducted in virtual reality, participants experienced this exact situation—a bottle moving up instead of falling down after being knocked over by a toy car. As a result, participants showed a more creative thinking style.

Experiences like these are called 'diversifying experiences'. They are unusual and unexpected events or situations that push people outside of the realm of normality. Research has shown that diversifying experiences, such as violations of expectations, mental or developmental adversity, and multicultural experiences, can elicit a more flexible way of thinking and are related to higher levels of creativity.

Schema-Violations

Diversifying experiences can push people outside of the realm of normality; this happens when people witness or experience targets, objects, or actions that are inconsistent with their expectations about the world. Diversifying events of this kind are called 'schema-violations'—events or experiences that disconfirm schema- and stereotype-based expectancies. When people have to navigate through a situation that is new and rather challenging, previously used schematic solutions no longer apply, making it necessary to look for alternative answers. Hence, new and alternative ways to solve problems are investigated, thereby increasing the chances of creativity and of embracing atypicality.

Contradictory or Paradoxical Information

Experimental studies have shown that schema-violations can be induced relatively simply by asking people to write down, or merely read, seemingly contradictory or paradoxical statements. For example, in one study, participants read a description of a problem, yet halfway through the description suddenly the information provided became inconsistent with the rest of the description. Creative ability was higher after reading these inconsistent descriptions, compared to descriptions that did not include inconsistencies. Interestingly, however, this effect was only found for people with high levels of problem construction ability, indicating that the ability to define problems in multiple, creative ways may be necessary to process this diverse or conflicting information.

In similar vein, after reading a product description that contained paradoxical information, creativity was enhanced relative to when the description contained only compatible information (Miron-Spektor et al., 2011). The latter effect also held when

people, instead of merely reading the paradoxical statements, actively formulated them themselves. In that case, the effect seemed to be mediated by both implicit and explicit sense of conflict associated with the paradox. Still another study showed that creativity is enhanced more after combining two concepts with many incompatible attributes. Participants had to solve either novel or ordinary conceptual combination problems. An ordinary combination included two concepts with many compatible attributes, like a piece of coat that is also a kind of animal skin (a leather jacket). A novel combination included two concepts with many incompatible attributes, like a piece of furniture that is also a kind of fruit (e.g., a banana-shaped sofa-bed), requiring participants to actively resolve the incompatibilities between the emergent properties of the concepts. In line with other studies on contradictory or paradoxical information, creative performance only improved after solving novel (as opposed to ordinary) conceptual combinations.

Counter-Stereotypes

Counter-stereotypes are another type of schema-violations that have the potential to influence creativity. For example, it has been shown that listing counter-stereotypic social category combinations (“overweight model”), as opposed to stereotypic social category combinations (“skinny model”), can lead to higher cognitive flexibility, less heuristic, and more indirect, to creative thinking (Godłowska et al., 2013). Furthermore, studies have shown that witnessing individuals in a counter-stereotypic environment can influence performance on creativity measures. That is, after looking at pictures of individuals in an unexpected environment (e.g., a priest in front of a mosque), creativity was higher than after looking at the same individuals in their expected environment (e.g., a priest in front of a church; Godłowska et al., 2014). Interestingly, studies suggest that the relationship between counter-stereotypes and creativity depends on personality factors such as personal need for structure, with only participants low in personal need for structure experiencing a creativity boost after being confronted with schema-inconsistencies. In line with these findings, using a task in which participants consistently indicated their preference for either a schema-consistent or schema-inconsistent image, both participants low in need for structure and high in openness to experience exhibited a higher preference for (i.e., likability) and approach tendency towards the counter-stereotypic, schema-violating pictures.

Real-Life Schema-Violations

Besides reading or writing paradoxical stories or statements like the ones mentioned above, or looking at pictures of counter-stereotypic events or environments, one can also experience schema-violations in real-life. Imagine, for example, that you just moved to another house, and it is your first time driving to work from your new home. Whereas earlier you could almost automatically drive to your work, now you have a little trouble finding your way. That is, your existing schema of how to get to work is almost completely based on the old route to work you drove so many times for years. Now, however, the route you are driving is inconsistent with this schema, and you are forced to adjust. Do creativity and levels of creative performance also enhance after these real-life schema-violating events? Several studies suggest they do.

It is argued that at times, perhaps in service of a specific goal (e.g., maintaining social relationships), humans are able to display bodily expressions that are contradictory to their mental states. In doing so, individuals experience a sense of incoherence indicating to the person that the environment is unusual, and that alternatives have to be considered. For example, normally, happy facial expressions originate within happy circumstances. However, when, for whatever reasons, sad facial expressions accompany happy circumstances, a sense of incoherence is experienced. Hence, individuals experience themselves in a schema-violating manner. Therefore, in testing whether this so-called ‘mind-body dissonance’ would subsequently improve levels of creativity (or embracing atypicality), Huang and Galinsky (2010) conducted four experiments, in which they either paired happy and sad memories or music with happy and sad facial expressions, or paired high- and low-power roles with high- and low-power postures. In doing so, they were able to show that mind-body dissonance stimulates people to flexibly expand their category boundaries, which can aid in creative problem solving.

In another study investigating real-life schema-violations, Ritter et al. (2012) had participants prepare a sandwich with butter and chocolate chips (a popular breakfast in the Netherlands) either in a well-known, routinely manner, or in a rather unusual, schema-violating way. Whereas those in the routine condition buttered the bread and then sprinkled the chocolate chips on top of the buttered bread, participants in the schema-violating condition first sprinkled the chocolate chips on a plate, buttered the bread, and then placed the buttered bread upside down on the plate full of chocolate chips. Those individuals who had prepared their sandwich in a schema-violating way demonstrated higher levels of cognitive flexibility on a subsequent task, compared to individuals who had followed their normal routine in preparing their breakfast.

In the same line of studies, Ritter et al. (2012) had participants experience even more rigorous schema-violations—violations of the laws of physics. While being immersed in virtual reality, participants either experienced three laws of physics (perspective, velocity, and gravity) being violated, or experienced the same events in a non-violating way. To be more specific, in the schema-violation condition objects became smaller in size while participants were approaching them, time seemed to fly (i.e., 1 step in virtual reality equaled a 2.5 change in environment), and instead of falling of a table as expected, a bottle slowly moved upwards in the air. Individuals who had experienced these intense and immersive schema-violations demonstrated a more flexible thinking style on subsequent measures of creativity, as compared to those who had experienced the corresponding normal events.

The examples described above suggest that schema-violations can arise in virtually every situation, ranging from being exposed to paradoxical information or counter-stereotypes, to disrupting a routine activity, to taunting the laws of physics. These

situations—as diverse as they are—have in common that people experience or witness something that is inconsistent with their expectations, hereby forcing them to embrace atypicality and to look for alternative answers. This can elicit a more creative thinking style. The question remains what the boundary conditions are of the relationship between schema-violations and creativity.

Boundary Conditions

Does every schema-violation facilitate creativity? Are there differences between various types of schema-violations and their influence on creativity? Do schema-violations always have a positive influence on creativity, or may the relationship sometimes be reversed? In the following section, different features of schema-violations will be discussed that may have an influence on creativity: intensity, valence, and level of engagement.

Intensity of schema-violations. As illustrated above, irrespective of their intensity, schema-violations can have an effect on creativity. That is, starting with smaller, weaker schema-violations such as reading paradoxical information, to bigger violations such as coming up with counter-stereotypes and violation of routines, to the biggest violations when the laws of physics are taunted, all studies seem to indicate the same: an improvement in creativity.

Valence. Whereas the schema-violations described above are relatively neutral (e.g., they are not particularly threatening), there are examples of schema-violating situations that have a negative valence. For example, in one study, participants witnessed a person being rude to another person—an act that can be considered as schema violating. Subsequently, levels of creativity decreased, rather than increased. However, this effect was mediated by negative affect. The authors argue that the negative affect caused a deficiency in encoding elaboration, thereby negatively affecting creativity. Perceiving a schema-violation as negative or threatening may, thus, have detrimental as opposed to beneficial effects on creativity.

Level of engagement. Another interesting feature of schema-violations involves the fact that they can be passively witnessed or actively experienced, leading authors to suggest that the relationship between schema-violations and creativity may partly depend on the level of engagement one has with the experience. The two studies of [Ritter et al. \(2012\)](#) described above (in which participants prepared a sandwich in a schema-violating order, and experienced the laws of physics being violated) also included a passive condition, in which participants did not experience the schema-violation themselves, but witnessed a film-clip of an actor encountering the schema-violation. Increased creative thinking was observed after active involvement in schema-violations or unusual events, but not after vicarious involvement (i.e., when simply witnessing a schema-violation or an unusual event). Moreover, [Ritter et al. \(2014\)](#) showed that participants' levels of cognitive flexibility increased after witnessing a film clip of an actor performing a sequence of actions in a rather unusual, schema-violating order (compared to a well-known order) but only when identification with the actor was high (i.e., when being immersed in the story, and when identifying with the actor performing the action). When identification with the actor was low (i.e., when merely focusing on evaluating the story and the performance of the actor), witnessing schema-consistent versus schema-violating sequences of actions did not influence creativity. These findings suggest that at least some level of engagement in a schema-violation is necessary for creativity to be enhanced.

Why Schema-Violations Influence Creativity

Although less is known about the theoretical understanding of the effects of schema-violations on creativity, authors have suggested that the experience of conflict or violation of expectations that arises with schema-violations, and/or a persons' ability to differentiate and integrate multiple perspectives (i.e., integrative complexity), can mediate the effect.

For example, research testing the effect of a conflict mindset on creativity has shown that when adopting a conflict (versus cooperation) mindset people develop more original solutions for conflict-related situations. Furthermore, adopting a paradoxical frame elicited a sense of conflict regarding this frame, both explicitly and implicitly, which subsequently accounted for its relationship with creative insight. In a similar experiment, participants also performed a writing task in which they were asked to write a story describing a picture. Used as a measure of integrative complexity, these stories were subsequently rated on the use of different or competing themes, and the connections between these themes. Results showed that adopting a paradoxical frame indeed increased participants' ability to differentiate and integrate multiple perspectives, and that this ability, together with sense of conflict, accounted for the relationship with creativity. Moreover, a study investigating the neural correlates of schema-violations has shown that activity in the temporal parietal junction (TPJ)—a brain region known to be involved in violations of expectations and unexpected environmental stimuli—was higher for participants who were watching a schema-violating event compared to participants who were watching the corresponding normal event ([Ritter et al., 2014](#)). Additionally, activity in the right TPJ was positively correlated with an increase in cognitive flexibility. These results indicate that schema-violations may enhance creativity because they break expectations, thereby enabling people to overcome mental fixedness.

Developmental Adversities

Another diversifying experience that can push people outside of the realm of normality and help them see the world in multiple ways may be the experience of developmental adversities. Especially research into the non-normative life experiences of eminent artists speaks to this idea, showing that diversifying experiences of artists may play a significant role in later creativity.

For example, in studies focusing on eminent creators, creative performance seems to have a negative relationship with psychological health (Simonton, 2014a), and eminent achievers in several domains appear to exhibit higher levels of psychopathology compared to the general population. As suggested by Simonton (2014a), the productivity levels of creative artists and ‘geniuses’ correlate positively with the incidence of mental problems. Notably, through extensive historiometric analyses, Damian and Simonton (2015) argued that, besides mental illnesses, more developmental adversities are also related to more lifetime creative achievement, but that this effect has been relatively overseen because most studies use samples with relatively few developmental adversities (i.e., majority samples). Therefore, based on analyses of biographical sketches of eminent African American achievers, these authors showed that the positive relationship between mental illness and creative achievement diminished when controlling for developmental adversity (parental death, poverty, and discrimination), indicating that developmental adversity had traded-off roles with mental illness as a diversifying experience in enhancing creativity. Importantly, it may not merely be mental illness or psychopathology, but instead, more general adversities during development, that can act as diversifying experiences in enhancing creativity. For example, archival research showed that eminent individuals experienced more demanding childhood experiences compared to an ordinary sample. Additionally, eminent creativity has been linked to experiences such as early orphan hood, being part of a minority group, or having had unconventional education.

Multicultural Experiences

Multiculturalism

Another type of diversifying experience that can influence creativity is experiencing multiculturalism, or multicultural experience. When people learn how things are done differently in other cultures, they are pushed outside the realm of normality, thereby increasing their chances of seeing things from multiple perspectives, thus stimulating flexible, creative thinking (Gocłowska and Crisp, 2014).

Multicultural experiences and their influence on creativity range widely. For example, recreational travel seems to increase creativity (De Bloom et al., 2014), but also working together with culturally heterogeneous groups causes a steeper increase in creativity as compared to working in homogeneous groups (particularly when the differences between groups are not made salient; Vezzali et al., 2016). Furthermore, membership in multiple groups is associated with greater creativity. Importantly, multiple studies on counter-stereotypes demonstrate that even thinking of diverse individuals can elicit higher creative performance (Gocłowska et al., 2013).

Multicultural Experience Survey

Leung and colleagues have developed the Multicultural Experience Survey (MES; Leung and Chiu, 2010), a questionnaire including items on living abroad, speaking foreign languages, and one’s immigration status, but also on one’s favorite cuisine (foreign or not) and the nationality of one’s favorite musicians and closest friends. Interestingly, higher levels of multicultural experiences, as indicated by higher scores on the Multicultural Experience Survey, are related to higher levels of creativity, and this relationship seems to be particularly true for individuals high on the personality trait openness to new experiences. On the other hand, for those individuals who are less open to new experiences, the relationship between multicultural experiences and creativity seems to be reversed.

Living Abroad

Another type of multicultural experience is the experience of living abroad. Studies have shown that people who have lived abroad achieve greater creative and professional success compared to individuals that have spent their whole life in the same country. This link specifically accounts for individuals who identify with both their home and host cultures simultaneously, compared to those who only identify with a single culture, presumably because the former have greater levels of integrative complexity—the ability to consider and combine multiple perspectives. Similarly, in an experimental study, being exposed to elements of two cultures simultaneously led to bigger increases in creativity than being exposed to elements of either culture separately (Leung and Chiu, 2010).

One critical aspect of the relationship between exposure to foreign cultures and creativity seems to be multicultural learning—learning about the host culture. One longitudinal study found that the extent to which MBA students learned about the culture of the country they moved to, predicted their ability to differentiate and integrate multiple perspectives, which subsequently predicted the number of job offers they got after graduation (Maddux et al., 2013). Furthermore, for those individuals who moved abroad, the relationship between time spent abroad and creativity was significantly mediated by adaptation—that is, the extent to which they learned how to behave and think in a different way (Maddux and Galinsky, 2009). Similarly, compared to learning something new about your own culture, creativity seems to increase more after learning something new about another culture, especially when the underlying reasons are also known.

In sum, a host of studies has demonstrated how identifying with, learning about, and adapting to multicultural experiences are related to creativity. That is, the diversifying experience of living abroad, or gaining multicultural experience, can broaden one’s view, and enable to literally and figuratively see multiple perspectives, thereby facilitating our creative thinking skills.

Are All Diversifying Experiences Positive?

Although most research focuses on the positive link between diversifying experiences and creativity, it is important to keep in mind that sometimes and some types of diversifying experiences can backfire—they can have a negative relationship with creative performance (for reviews see [Damian and Simonton, 2015](#); [Gocłowska et al., 2018](#)). One reason why this might happen is because when diversifying experiences are very intense, individuals may lose the ability to cope with those experiences. For instance archival analyses of the lives of great fashion designers revealed that some aspects of multicultural experiences, like the number of countries that one has visited, or the extent of cultural differences between these countries, have a curvilinear, inverted U-shaped link with creativity. These analyses revealed that while at low-to-medium levels of intensity multicultural experiences would benefit creativity, once a certain level of intensity was reached the relationship with creativity began to taper off or even reverse. A similar pattern has been suggested in archival research looking at how mental illness and racial minority status affected creativity of eminent African- and White-Americans ([Damian and Simonton, 2015](#)), and in research on mental illness among famous thinkers, writers, artists and composers ([Simonton, 2014a](#); for reviews see [Damian and Simonton, 2015](#); [Gocłowska et al., 2018](#)).

As a result, [Gocłowska et al. \(2018\)](#) postulated that the beneficial effects of diversifying experiences to creativity may be bounded by the intensity of diversifying experiences, as well as the personal coping resources available to individuals undergoing those experiences. Diversifying experiences of low to medium intensity should primarily be perceived as challenging, thereby increasing creativity, however diversifying experiences of medium to high intensity are more likely to be perceived as threatening, thereby decreasing creativity. Furthermore, the “sweet spot” at which diversifying experiences benefit creativity may vary from one person to another, and from one situation to another. With high personal adaptive resources individuals undergoing diversifying experiences are more likely to appraise those experiences as a challenge, thereby increasing creativity, whereas with low personal adaptive resources, they are more likely to appraise the same diversifying experience as a threat, thereby decreasing creativity. Hence, according to the diversifying experience model, the effects described in the current article may be bounded by diversifying experience intensity as well as individual’s coping resources.

Conclusion

In sum, diversifying experiences—unusual and unexpected events or situations that push people outside of the realm of normality— can elicit a more flexible way of thinking and are often related to higher levels of creativity. When people experience new and rather challenging situations, previously used schematic solutions may no longer apply, making it necessary to look for alternative answers. Hence, new and alternative ways to solve problems are investigated, thereby increasing the chances of higher creative performance. One type of diversifying experience that can arise in virtually every situation are schema-violations. Schema-violations can range from encountering paradoxical information, to being exposed to counter-stereotypes, to disrupting a routine activity. These situations, as diverse as they are, have in common that people experience or witness something that is inconsistent with their expectations, hereby forcing them to embrace atypicality and to adapt a more creative thinking style. Research has identified several boundary conditions of the relationship between schema-violations and creativity. For example, at least some level of engagement in a schema-violation is necessary for creativity to be enhanced. Moreover, perceiving a schema-violation as negative or threatening may have detrimental as opposed to beneficial effects on creativity. Developmental adversity (e.g., poverty, discrimination, early orphan hood, being part of a minority group, having an unconventional education) is another type of diversifying experience that can influence creativity. Especially research into the non-normative life experiences of eminent individuals speaks to this idea, showing that diversifying experiences of eminent individuals may play a significant role in later creativity. Moreover, diversifying experience can be elicited by multicultural experiences. Multicultural experiences and their influence on creativity range widely, from recreational travel, to working together with culturally heterogeneous groups, to living abroad. What they have in common is that people learn how things are done differently in other cultures, and they pushed people outside the realm of normality, thereby increasing their chances of seeing things from multiple perspectives, thus stimulating flexible, creative thinking. On the one hand, capturing all unusual and unexpected situations under the umbrella term diversifying experiences allows us to realize that a whole range of very different phenomena (extending even further than schema-violations, developmental adversities and multicultural experiences) are in one way or another linked to creativity and creative performance. On the other hand, however, it is important to keep in mind that every situation is unique, and therefore may have its own unique influence on creativity. Moreover, the relationship between diversifying experiences and creativity is not a static given, but may depend on the intensity, valance, and level of engagement with the situation.

Glossary

Bicultural Bicultural individuals have experienced and internalized two cultures

Closed-mindedness The need to have a certain answer

Cognitive flexibility The ability to engage multiple concepts simultaneously and adapt behavior to one's environment

Essentialism The view that women and men, or different racial groups have specific "essences" that make them what they are.

Integrative Complexity A high level of differentiation and integration of a plurality of perspectives

Diversity Definition

The term diversity refers to difference, and in this context a diverse system is one in which human beings that have been categorized as different from each other coexist. Common categories include race, gender, class, culture, ethnic origin, religion, and sexual orientation. Other relevant forms of diversity include cognitive diversity, and importantly diversity in attitudes toward diversity. Where diversity refers to the demographic fact of differences, pluralism is the intentional effort to engage diversity to create a mutually beneficial, generative social system.

Introduction

The relationship between creativity and diversity is complex. Historically cultural diversity has been a primary engine of innovation (Zachary, 2003). More mundanely, diverse groups come up with more uses for a brick than homogeneous groups. Culturally diverse groups also come up with more ways to prepare a chicken, whether Tandoori Chicken, Chicken Kiev, Pollo en Mole, or Pollo al Mattone, an Italian preparation involving a chicken flattened by, appropriately, a brick. Diversity can lead to creativity, but it can also lead to conflict and fragmentation. The term diversity is notably used in the context of prejudice, racism, systematic oppression, bias, and the "diversity trainings" created to address them. The creativity of diversity is by definition a social, interactive creativity, a multidimensional phenomenon that has psychological, interpersonal, and cultural dimensions. In order for diversity, understood broadly as demographic difference, to lead to creativity, it requires an intentional effort to find mutual understanding, bridge and leverage differences and remain open to the possibility of creation.

Diversity: Source of Problems and Source of Creativity

In the mid-20th century, humanistic psychologists like Abraham Maslow drew attention to the fact that the discipline of psychology had focused on humanity's pathological manifestations (what was sometimes referred to as "aggression and depression") but was much less knowledgeable about psychological health, well-being, and creativity. The focus on psychological health and optimal functioning was later followed by Positive Psychology. In the same way, the Indian political psychologist Ashis Nandy has pointed out that there is a "conspicuous asymmetry" between studies focusing on violence and those focusing on creativity or non-violent exchanges between different cultures and ethnicities (Nandy, 2002). Some media present dramatic stories of violent clashes

between groups, extremist over moderate voices, and tend to focus on violence. Creativity in the study of culture and religion can still be found in current affairs and in the research and practices of diversity.

One of the key problems facing the global discourse of diversity is that it is increasingly framed as a *problem*, and at best a problem to be managed (Montuori and Stephenson, 2010). The growing crisis of immigration, with refugees fleeing war zones, political and ethnic persecution and economic hardship has put a strain on some countries and has been one source of this approach. At the same time there has been a rise in authoritarian leaders around the world. Historically such leaders have used propaganda to demonize out-groups, often for the purpose of bringing a group or a nation together under the pretense of fighting a common internal or external threat. Authoritarianism always involves attempts to homogenize, hierarchize, and set up black and white alternatives, setting in-group against out-group. Around 60% of Americans believe the presence of people of different races, ethnic groups, and nationalities makes the United States a better place to live.

In organizations, diversity trainings attempt to instruct people in how to avoid being insensitive, abusive, stereotyping, offensive, and how not to break the law. There is greater awareness of the pervasiveness of racism, sexism, and prejudice based on sexual orientation and gender identity and bias toward other cultures and out-groups, and of incidents of prejudice. Thus it is perhaps not surprising that there is more emphasis on highlighting persistent and inexcusable injustice. The focus is on individual and collective problematic attitudes and behaviors and what can be done to avoid them. Nevertheless, the two dominant approaches to issues of diversity in the United States, “colorblindness” and multiculturalism, make both minorities and non-minorities feel excluded they have been found to be largely ineffective (Kalev et al., 2006; Plaut et al., 2018).

The real and the potential benefits of diversity, the articulation what a thriving diverse society or organization might be like, and the propagation of examples from history to illustrate how the creativity of diversity has fueled human flourishing have not received the attention that racism, sexism, and other forms of discrimination have. There is scant popular awareness of the historical role of creative diversity in such key places and times such as The Gupta period of India, Periclean Athens and the rich culture of the Mediterranean, the reign of the Kangxi emperor, Florence in the Renaissance, Al-Andalus, the Silk Road, the exchanges across the Indian Ocean, Vienna at the turn of the 20th century, and many other significant examples of cultural creativity. While certain places and times have been recognized and studied as particularly significant moments in human history, creativity research has not engaged with them extensively. Indeed, creativity researchers have only recently begun to address the complexities of social and cultural creativity (Simonton, 2003).

Disciplinary fragmentation has meant that research on the interaction of creativity, culture, and diversity can be found scattered in a wide range of disciplines such as Cultural Studies, Ethnic Studies, Women’s Studies, and History. These disciplines are often not informed by what is traditionally known as creativity research as documented in this encyclopedia. Creativity research is in a position to make a substantial contribution to the discourse and practices of diversity, and the challenge of diversity also involves diversifying creativity research itself by making it more transdisciplinary, in dialog with a range of other disciplines, and with a more diverse cast of researchers. A brief overview of creativity and diversity in groups and culture gives a sense of the range and scope of the existing research and the opportunities that lie ahead.

Groups and Cultures

In the United States historically groups were frequently associated with the phenomenon known as groupthink, which is in fact quite antithetical to creativity (Janis, 1983). Creativity was associated almost exclusively with individuals, which meant relationships and exchanges were not researched. Research on creativity in groups is a relatively recent phenomenon sparked to some extent by the interest in creativity and innovation in industry where the value of creative groups is great. The study of creative groups in jazz and more generally in the arts has also contributed to the development of this field (Sawyer, 2006) (See Teams).

The phenomenon of groupthink is particularly interesting because it involves a number of factors, all of which conspire to homogenize the group, eliminate diversity of perspectives and creativity. They include:

- The unwillingness to examine anything but a few alternative courses of action, often only two, without a survey of the full alternatives;
- Failure to examine the course of action initially preferred by the majority of the members from the standpoint of non-obvious risks and drawbacks that had not been evaluated originally;
- Neglect of courses of action initially evaluated as unsatisfactory by the majority;
- Little or no time is spent discussing whether non-obvious gains have been overlooked or whether the ways of reducing seemingly prohibitive costs which make alternatives undesirable;
- Few if any attempts to obtain information from experts who can supply sound estimates of losses and gains to be expected from alternative courses of action;
- Selective bias is shown in the way the group reacts to factual information and relevant judgments from experts, the media, and outside critics;
- Members take interest in facts that support their initially preferred policy, and take up time in their meetings to discuss them, but they ignore facts and opinions which do not support their policy;
- Members spend little time deliberating about how the chosen policy might be hindered by bureaucratic inertia, sabotaged by political opponents, or temporarily derailed by the common accidents that befall the best of plans.

Groups that become victims of groupthink have already made up their minds and are unwilling to listen to any other views. There is a pressure to conform and go along with the group consensus. In terms of the creative process, they cannot accept divergent thinking, because they have already converged on the right policy or plan. Victims of groupthink therefore eliminate creativity altogether to the extent that no diversity of perspectives or alternatives are encouraged. The group process to some extent displays processes that occur at the individual level but writ large. "Premature closure," or the unwillingness to explore alternatives after the initial diagnosis, is the most common error in medical diagnoses, for instance. Minority dissent on the other hand stimulates creative thinking, as does an insistence of maintaining a diversity of perspectives in the group (Nemeth, 2018).

There are many ways that diversity fosters creativity. A diversity of background, knowledge, and perspectives enhances creativity in groups. The presence of group-members with diverse perspectives can lead to more creativity and problem-solving ability than a group of experts. A dramatic example occurred when Eli Lilly created a Website where members of the public could engage with scientific problems that the company's researchers were facing. The company promised a financial reward for the solutions to the problems, which ranged from breast cancer risk assessment to the detection of organic chemical vapors to tracing metal impurities (Page, 2008). The success rate of this approach was remarkably high, and now open-sourced and distributed problem-solving have become significant sources of innovation. The reason why they work is because when problems are complex, diversity trumps ability.

Teams can have cognitive differences, which is one form of diversity. These differences can include different perspectives, or ways of representing situations or problems; different interpretations, or ways perspectives are categorized; diverse heuristics, or ways of creating solutions for problems; and diverse predictive models, which address cause and effect. A positive atmosphere, and an absence of relational conflict are important, but challenges and stress are also needed to bring the best out of the group. Differences of perspective can lead to conflict, and yet it is not the content of the conflict that is most important but the way it is addressed. In fact, conflict can even be generative, and lead to more creativity. In order to be creative, diverse groups have to be creative about their diversity and about how they get along. Cultural and more broadly demographic diversity can also be beneficial for group creativity. In order for demographic diversity to be beneficial, the group needs to be motivated to make it work and needs to work together to create trust. Having respect for the ability of others is an important factor in establishing a foundation for diverse groups. This takes us back to the difference between diversity, which refers to the fact of diverse elements in any system, and pluralism, the intentional effort to engage diversity to create a mutually beneficial, generative social system. The creative group or organization or society is itself a creation (See Group Creativity).

Creative groups are marked by paradoxical relationships found in the form of both/and creative tensions. R&D scientists for instances have been shown to want autonomy *and* interaction, specialization *and* broad interests, the pursuit of interested problems for their own sake *and* practical results. Belbin's work addresses the importance of experiential diversity in groups and proposes a specific set of roles in a group facilitates the creative process. The roles are the Plant (or Idea-generator), The Shaper who shapes and drives the process, The Resource Investigator who finds and mobilizes resources, The Coordinator, who ensures equitable participation, The Specialist, who brings technical knowledge, The Monitor-Evaluator, who acts as critic, The Implementer who focuses on the product, The Completer-Finisher who acts as the detail person, and the Team-Worker who maintains morale and cohesion (Belbin, 2012). Whether or not groups actually include the broad range of diverse perspectives, roles, and aptitudes Belbin suggests, his research indicates that the right mix of diverse experiences and capabilities is helpful in a group.

Diversity has consistently contributed to musical innovation. Port cities from Lesbos to Liverpool, New Orleans, Havana, Kingston, Rio de Janeiro, Salvador da Bahia, and Venice have always been centers of musical innovation (Gioia, 2019). A multicultural mix has always led to a thriving musical scene. Port cities and multicultural communities have always benefited from the exchange of people and ideas, from traffic, visitors, and ideas. Simonton (Simonton, 1997) summarized this by writing that "a pluralistic cultural milieu will more likely infuse a developing talent with the capacity to conceive new combinations of concepts and techniques that will support historically significant innovations" (p.92).

Sometimes the diversity takes the form of actual physical encounters between people of different cultures, and other times it has been the ideas and more generally the products of one culture that influenced another culture. While Paul Gauguin actually went to Tahiti, Van Gogh never went to Japan, but he was deeply influenced by the work of Japanese painters whose work was beginning to be exhibited in Europe's major centers. Fascinating loops of influence are created. In the 1950s and 1960s, musicians in England and African nations such as Mali and Nigeria heard American blues, jazz, and rock, and were influenced by them. The British Invasion brought bands like The Beatles and The Rolling Stones to the United States, and they in turn influenced generations of American musicians. Musicologists and musicians such as Ry Cooder traveled to Mali to hear how African music has been at the roots of American blues, brought over with slaves, and performed with Malian musicians.

Jazz and Openness to Diversity

Jazz is considered to be one of America's greatest contributions to the arts. It originated at the beginning of the 20th century in New Orleans, a city with a rich diversity of cultural influences. In the case of jazz, these influences included complex African rhythmic and improvisational traditions, European instruments and harmony, substantial contributions by often conservatory trained Creoles (free Blacks who spoke Spanish and French), as well as the Black Church and Tin Pan Alley songwriters, many of whom were Jews of Eastern European descent.

Jazz emerged out of the interaction of musicians from many rich and diverse cultures and musical traditions working together in an environment that offered many opportunities to perform. It has continued to be an open, interactive musical tradition, continuing to draw on a plurality of other musical styles. Jazz has been an open system, where innovators and conservatives have been in continual dialog and as a result, it has developed many significant sub-categories. A number of musicians drew explicitly from Western classical music. For instance, Duke Ellington recorded Tchaikovsky's *Nutcracker Suite* and Grieg's *Peer Gynt*, Charlie Parker recorded the lush *Charlie Parker with Strings*, and Miles Davis's recording *Sketches of Spain* included the second movement of Spanish composer Joaquín Rodrigo's *Concierto de Aranjuez*. Latin Jazz continues to be an important branch, first brought to popular attention by the Juan Tizol composition *Caravan* for the Duke Ellington band, and then the popular work of Dizzy Gillespie and Stan Kenton. In the 60's the Bossa Nova sound exemplified by the classic and commercially successful recording by Stan Getz and Antonio Carlos Jobim, *Girl from Ipanema*, led to the incorporation of Brazilian rhythmic and harmonic sensibilities. The Third Stream movement involved the incorporation of elements from European classical music, most notably in a traditional small group setting, with the Modern Jazz Quartet being perhaps the most notable example. Leading figures such as Miles Davis, Herbie Hancock, Chick Corea, and groups such as Weather Report, Headhunters, and Return to Forever incorporated elements from rock and funk. Weather Report's Joe Zawinul led *The Zawinul Syndicate*, an innovative band that over the years has included musicians from several continents including vocalist Sabine Kabongo from Belgium and the Congo, drummer Paco Sery from the Ivory Coast, percussionist Aziz Sahmaoui from Morocco, percussionist vocalist Arto Tunçboyacıyan from Turkey, and guitarist Amit Chatterjee from India. Herbie Hancock's *The Imagine Project* album featured collaborations with musicians such as Ireland's The Chieftains, Indian sitar player Anoushka Shankar, Malian singer Oumou Sangaré, and others.

The challenge with these projects that bring together diverse musicians who often very different musical backgrounds is the integration in a cohesive whole where, once again, the whole is more than the sum of the parts, rather than less. While these two projects have been successful, is certainly not the case that every such effort at bringing musicians from different cultures has been equally successful. Research on group creativity is in its infancy compared to research on creative individuals, but the challenge of diversity with all its potential makes it an even more urgent task.

The changing styles that emerge from these interactions are reflected in the changing categories of the Recording Academy's Grammy awards, music's equivalent of the Oscars. In the 1960s and 1970s, there were obviously no categories for rap, since the genre had not yet been created. The categories are determined largely by the number of submissions in each one, and therefore reflect the popularity of different styles. Certain categories grow and others shrink or even disappear, and controversies have developed about the loss of certain categories, such as the temporary disappearance of Latin Jazz, and the criteria for categorizing music. It is hard to assess how to categorize the increasing number of recordings that span multiple categories, such as rap and metal, or works with American and African musicians that trace the African roots of the blues in Mali. Ever more capacious umbrella terms such as Roots Music have been used to encompass multiple genres of music. A term like "world music" essentially embraced a huge number of genres and artists from all over the world simply by setting them in opposition to popular music in the United States and to a lesser extent Europe. The term has come in for criticism because it reflects an attitude that marginalizes any non-Western music as "the rest."

Continuing musical cross-pollinations also point to areas of potential controversy when it comes to the relationship of creativity and diversity. The evolution of music through interactions and blending of styles and categories raises complex questions about authenticity and appropriation. There is a long history of musical appropriation where, for example, styles that originate, in the African American musical tradition are appropriated by white performers who benefit financially from them in way that the original artists never did. While the idea of musical or other cross-pollinations may be appealing and contribute to a sense of an emerging global culture, matters are never as simple as that. The American singer-songwriter Paul Simon worked with South-African musicians to record his extremely successful album *Graceland* (1986). At that time there was an artistic embargo on South Africa in protest against the *apartheid* regime. Simon's decision to record with the South African musicians of Ladysmith Black Mambazo was very controversial and illustrates a tension between creativity and ethical and political concerns. Besides being a musical success, Simon's recording did a lot to draw attention to South Africa's enormously creative musical tradition, and the shameful *apartheid* policies but opinions are still divided about his decision.

Musical performance and music appreciation can bring people together. Interactions and friendships between members of different groups, or cross-group friendships, can promote positive attitudes toward other groups and reduce prejudice. The effect extends to people who know others who have cross-group friendships (Davies et al., 2011). In the case of diverse groups coming together for purposes of musical interaction across cultures there is typically a mutual respect for musicianship, a feeling of friendship among musicians and a sense of belonging to the same "tribe" (musicians) regardless of ethnic or national background. The experience of working with people one respects leads to the possibility of friendship and a diminution in prejudice. Creative collaboration, in this case in a musical context, is therefore a model for the process of bringing together people from widely different backgrounds. Engaging in a creative activity with people from different groups can therefore serve as a way to bring people together, create positive attitudes, and the effect can spread to people who are not directly involved in the activity.

Culture and Creativities

Creativity is not conceptualized and experienced in the same way throughout the world. China and Japan offer particularly useful examples of perspectives that are different from the American view of creativity. With the increasing emergence of a planetary culture

it is becoming clear that there are diverse ways of understanding creativity, and a range of creative practices. If the current definition of creativity is reduced to “original” and “authentic” as some Western scholars have recently suggested, these terms still appear to resonate in different ways in China and the United States, for instance (Niu and Sternberg, 2006). Creativity offers a fascinating lens to understand differences between cultures, and the differences can at times be dramatic. Chinese cosmology does not focus on cosmogony, or the origin of the Universe, but on the interconnectedness of all of existence, and views the cosmos as a process of continuous creativity (Tu, 2007) (See Regional Creativity: Asia).

The related concept of “originality” illustrates some of the differences. In the West, the value of the original, such as an original Picasso, simply cannot be compared to a copy no matter how good. The value of the original also depends on its condition. The better the condition, the cleaner the work, the higher the value. Chinese masterpieces, on the other hand, are regularly overwritten by scholars and collectors, who add inscriptions and seals. The work is always transforming, and the more famous it is the more it transforms. It would be hard for a Westerner to imagine the Mona Lisa with hundreds of years’ worth of inscriptions and seals, or to conceive of it as still changing and transforming.

The Ise Grand Shrine is a Shinto temple in the city of Ise, Mie Prefecture in Japan. It dates to 4 BCE and is dedicated to the Sun Goddess Amaterasu. For the Western visitor, a particular detail makes the shrine unusual: it is torn down and rebuilt every 20 years. If the Colosseum in Rome were to be torn down and rebuilt (in its original splendor) every twenty years, it would somehow not be the Colosseum for the Western visitor. It would be more like something one might find in Disneyland or Las Vegas, certainly not a national treasure as it is in Italy.

In China the term shanzhai is a neologism that describes a “fake.” Shanzhai cell phones may be sold under the brand Nokir or Samsing (rather than Nokia or Samsung), sports equipment may be sold with the name Adidos. They are considered to be just as good—and at times even better—than the “originals,” and may even contain notable improvements. There are shanzhai versions of Harry Potter stories (*Harry Potter and the Porcelain Doll*), with Chinese characters featuring the evil Yandomort. Shanzhai iPhones are sold as iPncne, which looks like faded lettering. These items are said not to be inferior to the “original,” and in fact are celebrated for their play on the “originals.” In the West, the Harry Potter story would be considered fan fiction, but Chinese culture does not have the same worship for the original, and may be interpreted as simple plagiarism, deception, and copyright infringement (Han, 2017). The moral and interpersonal dimensions are of much great importance in the Eastern view of creativity. The view of creativity is much broader and takes into account social and cultural contexts, focusing on appropriateness in ways that reflect a culture that not individualistic (Niu and Sternberg, 2006).

Attitudes Towards Diversity

While certain individuals are open and indeed fascinated by diversity, others tend to fear and reject it. One of the terms that is most closely associated with diversity is prejudice. Extensive research on the psychology of prejudice, racism, and authoritarianism has presented a rich and disturbing picture. Writing in the classic *The Authoritarian Personality*, Elke Frenkel-Brunswik (Adorno et al., 1950) compared findings on individuals who were prejudiced with those who were not. She stated that it is perhaps mainly the readiness to include, accept, and even love differences and diversities, as contrasted with the need to set off clear demarcation lines and to ascertain superiorities and inferiorities, which remains as the most basic distinguishing criterion of the two opposite patterns (pp.485–486).

In other words, when confronted with differences and diversities Authoritarian individuals feel the need to erect walls, metaphorical as well as literal, and establish who is on top, as opposed to successfully integrating differences, as we saw in the example of jazz musicians.

Frenkel-Brunswik articulated a central difference between prejudiced and non-prejudiced, but also between authoritarian and creative persons. It reflects two different ways of being in the world, and certainly two radically different relationships to diversity. Based on extensive research from political and social psychology as well as creativity research, there is a profile of authoritarian individuals who are closed-minded, intolerant of ambiguity, who think in rigid categories and dichotomies, and approach diversity and complex situation with quite relentless and unrealistic simplicity, focusing above all on establishing who is strong and who is weak, who is superior and who is inferior (Montuori, 2019).

Followers of authoritarian leaders crave cognitive closure, meaning that they want a clear and certain answer—any answer—when faced with complex phenomena. When faced with phenomena that are diverse, different, and ambiguous, they want clarity and certainty. They stick with a fixed view and are prone to overgeneralize and stereotype. The world is seen dualistically, in terms of black and white. Solutions are arrived at as soon as possible, in order to avoid ambiguous and unstructured situations that can lead to anxiety, discomfort, and fear. Diversity, or a plurality of perspectives, is viewed as a problem to be resolved: there is only one right way, one source of authority, and any other perspectives are not only wrong, but in all likelihood bad and threatening.

Milton Rokeach’s concept of dogmatism, which he felt represented a generalized authoritarianism better than the original 1950s study, showed that shared belief is a more important factor in social discrimination than belonging to a shared ethnic or racial group. Dogmatic persons cannot tolerate the coexistence of different belief systems, resist changing beliefs even when faced with information that invalidates them, and appeal to authority to support beliefs (Rokeach, 1954). The increasing complexity of diverse perspective stresses the ability to integrate phenomena, and one way to deal with that is to inhibit the emergence of the higher level of complexity, by not allowing them into consciousness. These are characteristics of prejudiced, authoritarian individuals. They are low on integrative complexity, less curious, and seek to eliminate diversity.

In his classic on the psychology of prejudice Gordon Allport argued that generalizations are a natural way to simplify a complex world. The key difference between the normal use of generalizations and prejudice is that prejudiced persons do not change their minds when confronted with information that disproves their beliefs. The person who is not prejudiced remains open to the possibility of change, whereas the prejudiced person does not.

At the other end of the psychological spectrum one finds individuals who are high on integrative complexity, open to experience, tolerant of ambiguity, have independence of judgment and complexity of outlook. As Frenkel-Brunswik put it, they include, accept, and even love differences and diversities. These are creative individuals, who also tend to be more cosmopolitan and less ethnocentric, curious about difference and diversity, more interested in other cultures and a multiplicity of perspectives. They view diversity and multiple perspectives as a source of creativity, rather than as a threat, and are open to changing their minds.

Particularly relevant for this discussion of diversity is Integrative Complexity, which addresses the complexity of information processing and decision making (Tuckman, 1966). Integrative complexity reflects the degree of differentiation and integration of multiple perspectives. Individuals who are low on integrative complexity see the world in black and white terms, avoid ambiguity and multiple possibilities. They stick with a fixed view, overgeneralize, and stereotype. Stereotypes simplify the complexity of the world. They place large numbers of people in a category and avoid the ambiguity of having to navigate the unknown and learning about a specific person, for example. Learning about a person may bring the knowledge that they do not conform to a pre-established, stereotyped view of the category of people they belong to, and this is something to be avoided because it might challenge deep-seated beliefs and ways of ordering and evaluating the world. Individuals with high integrative complexity perceive a diverse world with many alternatives. They view the world in a flexible and complex way and can respond in appropriate and novel ways. There is a strong positive relationship between high integrative complexity and creativity.

A further diversity-related contrast between authoritarian and creative individuals pertains to gender. Authoritarians often have very rigidly polarized conceptions of masculine and feminine roles. They can be described as oppositional identities. A man is a man to the extent that he does not engage in behaviors or express feelings that are associated with women, and vice versa. Authoritarian individuals have a strong focus on boundaries and reject ambiguity—as Frenkel-Brunswik put it, the need to set off clear demarcation lines and to ascertain superiorities and inferiorities—and as a result, anything that creates ambiguity in gender role and sexual identity is rejected outright.

In creative persons we find the opposite is true: The personality characteristics historically associated with men and women are not nearly as strong in creative people. Creative women, for instance, have been found to have fewer traditionally feminine interests, and more generally Barron (1972) wrote that “sex-specific interests and traits that are descriptive of men and women in general seem to break down when we examine creative people” (p.33). The authors of the classic authoritarian personality research found that whether one accepts tendencies of the opposite sex in oneself or not was an issue of great importance because these attitudes are generalized and projected into the social sphere. This is seen in the way that in authoritarian or religious fundamentalist regimes and communities gender roles are immediately differentiated (in terms of superiority/inferiority) very clearly, whether in Nazi Germany or Iran after the revolution. There is a rigidity in roles that reflects the overall rigidity found in authoritarian individuals, compared to the greater openness and flexibility of creative individuals.

Travel and Culture: Diversifying the Mind

Individuals who are exposed to a wide variety of perspectives are more likely to realize the arbitrary nature of any particular cultural norms and values, whether intellectual or aesthetic, and thereby impose fewer restrictions on the scope of their creative imagination (Simonton, 1997, p.92, p.92)

It is said that travel broadens the mind, and multicultural experiences can in fact enhance creativity (Leung et al., 2008). But this doesn't mean that every brief holiday on a foreign beach necessarily increases creativity. A deep immersion in a different culture combined with reflection on the experience can make the difference. Bicultural individuals who have experienced and internalized two (or more) cultures, have greater ideational fluency and tend to be more creative, and there is a proportionally large number of first and second-generation immigrants among eminent artists, inventors, and scientists. Exposure to another culture is a way of diversifying. Exposure to often radically different cultural norms and values can lead to an understanding of the extent to which these norms and values, whether political, cultural, intellectual, or aesthetic, are not absolute, but rather human creations. As a result of this exposure the world is seen as less fixed, more fluid and open. These multicultural experiences show that what was thought to be fixed and given, or “just the way things are,” is not always the case. On a very basic level this offers more choices, greater differentiation, and the ability to see the world from more than one perspective. This in turn allows for more and different connections between disparate elements, and fosters creativity.

Individuals who have *essentialist* views of racial groups believe that there are fixed underlying racial essences. They see all individuals that they identify as belonging to a specific race as having the same fundamental characteristics. Others believe racial categories are socially constructed, in which case the differences ascribed to races are the result of historical events that emerged over time and were influenced by cultural and political perspectives, as well as the science of the day. The belief in racial essences leads to more use of stereotypes. Inferences are made about a person on the basis of one distinctive trait such as skin color or gender. Essentialism induces closed-mindedness and reduces domain-general creativity (Tadmor et al., 2013).

Closed-mindedness involves the desire for certain knowledge, as soon as possible, and to maintain it as long as possible (Kruglanski, 2013). Closed-mindedness is clearly hostile to diversity and creativity, because creativity requires what the poet John Keats called negative capability. This involves being able to stay with intellectual confusion and uncertainty and not wanting certainty as soon as possible. Wanting to maintain one's certainty as long as possible also points to remaining closed to the possibility of revising one's knowledge in the face of contrasting information.

One illustrative and dramatic event in which fixed views about norms, values, and everyday habitual practices can be loosened is culture shock. Culture shock is a phenomenon widely considered to be an unpleasant side-effect of sojourns in other cultures. Whether traveling for business or pleasure culture shock was certain to ruin the trip. Nevertheless it has been argued that the experience can shed some light on what can happen in cross-cultural experiences, and that culture shock can lead to a better understanding of one's identity, to cognitive and personal growth, and that creativity plays a role in the process (Montuori and Fahim, 2004). Culture shock involves the experience of a gradual accumulation of events that shake up what is considered normal. As a result, there is a loss in self-efficacy with a breakdown in habitual behaviors and ways of making sense of the world. The term culture shock can be misleading because it gives the impression that it may involve one major shocking event, when in fact it is the gradual accumulation of a series of small events that makes people feel they have lost their grip on life. It is when people are suddenly confronted with an inability to deal with the things they take completely for granted in their own culture, and the number of these breakdowns steadily mounts, then culture shock sets in.

Culture shock is an extreme example of a process that leads to an awareness that very different realities exist to the ones people take for granted and are accustomed to. Things that remain unquestioned in one's own culture, activities in which it is possible to engage in habitual and unreflective behavior, turn out to be quite different in other cultures. Breakdowns occur in our habitual patterns of thinking and doing, and these breakdowns offer people an opportunity to learn about themselves and their own culture, as well as the new culture they are visiting.

This process highlights how cultures are in fact largely human creations. One of the most important insights that can come about as a result of immersion in other cultures is a relativizing of one's own culture and one's own experience. Experiencing diversity that challenges expectations encourages greater tolerance, creativity, and benefits intergroup relations. Multicultural experiences, and more dramatically, culture shock, are intense diversifying experiences, unusual and unexpected the events that violate our cognitive schemas and can promote cognitive flexibility.

Creative individuals exhibit more openness for experience, and so actively seek out other perspectives. Individuals who are lower on integrative complexity reject the multiplicity of perspectives by placing them in a hierarchy, whereby perspectives other than theirs are viewed as inferior. Multicultural experience reduces the need for cognitive closure and can "unfreeze" bias toward out-groups. This is attenuated by environments that strongly evoke the need for cognitive closure with an existential threat or when for some reason individuals are highly motivated to have definite knowledge. A way to heighten fear of difference and diversity and keep out-group bias frozen, therefore, is for authoritarian leaders to use propaganda to promote the existence of an existential threat coupled with a great deal of social insecurity (See Travel).

Diversity and Inclusion in Creativity Research

Creativity research has historically not drawn on a very diverse sample of the population, and for the first 40 years after J.P. Guilford's presidential address that kick-started research in the psychology of creativity, creativity researchers themselves were also almost entirely white, mostly American men, who researched other white men who had been identified as creative. It is also the case that most of the research in the psychology of creativity was conducted in the United States and focused on finding and studying exceptional individuals in specific elite domains in the arts and sciences.

The creators and thinkers featured in two classic edited books with leading creative figures as well as creativity researchers, Brewster Ghiselin's *The Creative Process*, and *The Creativity Question* by Rothenberg and Hausman, are almost entirely male and completely white. Historically in Europe and the United States individuals considered eminent creatives such as Nobel-prize winners, and great composers, artists, and novelists, were almost entirely men. Women have received far less attention than men in creativity research, and there is relatively little research on creative people of color. The mythology of genius, which dates back to Romanticism and has remained quite pervasive into the 21st century, included the notion that genius would overcome all obstacles (Montuori and Purser, 1995). This implied that social factors are not relevant and do not get in the way of the real genius, who will be recognized no matter what the circumstances. Consequently, if people of color and women did not become eminent creatives it must have been because they were not creatively brilliant enough, not because they were not given the opportunity to participate in the very domains where one could be recognized as a genius. Any explanation for their absence could be sought "inside" them, in their personality, cognitive style, motivation, or perhaps the nature of the "female brain," or the "race."

Anne Roe was the one of the first women to engage in systematic creativity research, at a time when there were few women researchers. Her research on eminent scientists was first published in 1953. It is telling that when she received tenure at Harvard in 1963, she was only the ninth woman to become a tenured faculty member, and the first woman to receive tenure in the Harvard School of Education. This should put the paucity of women in Ghiselin's book, which was published in 1954, somewhat in perspective, and also point to the slow but significant changes.

Barron's research on student artists at the San Francisco Art Institute already pointed to some interesting differences in the ways men and women viewed themselves as artists (Barron, 1972). The men stated that art was their whole life and that they could not

conceive of being anything other than artists. The women had a broader, more diverse view of themselves, putting friendship and family as equally important in their lives. The stereotypical image of the artist would suggest that compared to the women who appeared less fully committed, the men with their explicit passion, focus, and commitment would be the better artists. But when the work was presented to judges anonymously the women's work was judged to be equal in quality to the work of the men. This clearly reflects how some of the cultural assumptions and myths about creativity and the creative process are products of a particular time and place. They may not have directly affected the creativity of the women at the San Francisco Art Institute, but there is no doubt that cultural assumptions about the who, how, where and when of creativity have been a serious impediment for women.

Ravenna Helson argued that in order to understand the creativity of women a different approach to research was needed, one that focused more on the social world, not least because society historically actively prevented women from participating in domains such as science and the arts where one could achieve eminence. Her proposal, more recently embraced by researchers with an interest in social creativity and the socio-cultural approach, should also be applied to the development of a better understanding of traditionally under-represented groups in creativity research.

The focus of much creativity research has historically been on individual creativity (novelists, composers, individual scientists, the "lone genius") and not on the performing arts. This has meant that in the United States until recently there has been little research on creative groups and more broadly on creative interactions. The contribution of African-Americans to America's pre-eminent native art form, jazz, has gone largely unaddressed in the research. Eminent African-American creators have been profiled and studied but not in what is traditionally viewed as creativity research. Creativity research has found that there are few differences in creativity between African Americans and European Americans, and they have been found to tend to favor African Americans (Kaufman, 2006). Interestingly, African Americans were less likely to fall prone to gender stereotypes in creativity. In addition, African Americans and Native Americans tend to rate themselves as more creative than other ethnicities.

The historic absence of women and people of color in lists of eminent creatives is clearly attributable to social conditions that simply did not allow them access to the domains where it was possible to become an eminent creative. No representation without participation. As more women and people of color are participating in the rarefied domains in science, business, and the arts, where one can get recognition for outstanding contributions, they are now appearing in lists of eminent creatives. Nevertheless, there are still domains where women and people of color are conspicuous by their absence, and where they are still excluded in subtle and not-so-subtle ways. Minority students continue to be under-represented in programs for gifted students. Identifying these gifted students becomes a vital task, but the way they are identified is through standardized tests which are known to be problematic, since there are significant differences in aptitude and ability between ethnic groups and critics have also stressed how cultural differences make the tests less applicable. In order to do justice to the complexity of diversity, creativity research will also have to question and diversify its own fundamental assumptions and research methods.

Conclusion

The relationship between creativity and diversity is a fascinating one and a timely subject for research. There are individuals who are not open to diversity and feel threatened by it, as history, current events, and extensive research on all forms of prejudice shows. Research suggests that individuals who are more open to embracing diversity are also more creative, and that experiences of cultural diversity can promote creativity.

The relationship between creativity and diversity suggests a wealth of possible research opportunities. Topics include the differences between creative and prejudiced individuals, what makes individuals more open to diversity, how to educate for openness to diversity, the study of populations who have been under-represented in creativity research, what makes diverse groups, organizations, cities, and cultures creative, how different cultures develop different understandings of creativity, and more. This research will need to address a lot of interconnected phenomena and levels of analysis. As it will cross a wide range of disciplines, it will by necessity have to be inter- or transdisciplinary, and should encourage creativity researchers to collaborate with colleagues in disciplines where some of the above questions have been addressed already, albeit usually without drawing on the extensive research on the psychology of creativity. Not surprisingly, diversifying creativity research raises a lot of fundamental questions, as any cross-cultural experience raises questions about one's own culture. The definition of concepts like creativity, originality, innovation, and social creativity, will be contrasted with other views, and it is to be hoped that creativity researchers, an increasingly diverse group, will engage these possibilities with alacrity.

Introduction

Single-factor theories of creativity, like single-factor theories of intelligence, are very appealing because they allow one to paint the full picture of creativity—or at least a large part of it—with a single brushstroke. If creativity were a general trait or a single set of cognitive skills that influenced creative performance of all kinds, it would be much easier to understand, train, and test creativity.

Although single-factor theories of creativity have been popular for many years and have long dominated creativity assessment, there is growing evidence that they may not explain creative performance across a wide variety of content domains as well as more narrowly defined, domain-specific theories and assessment techniques. In fact, there is considerable evidence suggesting that the skills underlying creative performance are not even so general as to span the many tasks that make up such common content areas as the verbal, mathematical, or artistic domains. This task specific (or microdomain specific) view of creativity argues that the skills that lead to creativity on one task in a broadly defined domain of knowledge, such as writing, are not the same (and show little overlap with) the skills that lead to creativity in another task within the same writing domain. Thus, for example, poetry-writing and story-writing creativity may not rely on the same set of cognitive skills, and creativity in writing plays might call on yet a third distinct set of creativity-relevant writing skills.

Such a fragmented approach to creativity, in which every domain (or even every narrowly defined task within a domain) relies on its own unique underlying set of traits or skills, is naturally less satisfying than a grand, all-encompassing theory of creativity. The most widely held general view of creativity, which posits divergent thinking to be a general, domain-transcending skill applicable in all areas of creative endeavor, has been popular in creativity theory, training, and testing for many years, and despite doubts raised regarding the possible validity of *any* general theory of creativity by new research suggesting that creativity must be domain specific, divergent thinking theory continues to be used widely both in education and psychology.

After outlining the evidence for domains of creativity and current understandings of domain specificity and domain generality, this article will conclude by examining the implications of domain specificity of creativity for creativity theory, testing, and training. It will also consider theories that bridge generality and specificity and discuss how a newly emerging metatheory of creativity that is rooted in a modified divergent thinking theory and that incorporates a domain specific view of creative-thinking skills can replace earlier general theories as a unifying idea in creativity theory, training, and testing.

Domains and Domain Specificity

The concept of a domain as a set of representations or understandings underlying comprehension of a specific area of knowledge and performance of the tasks associated with that domain is, at the conceptual level, a fairly clear one. Applying this definition in a way that demarcates domain boundaries can be a much more contentious exercise, however.

In 1983 Howard Gardner published *Frames of Mind: The Theory of Multiple Intelligences*, and the domains (or, as Gardner termed them, “intelligences”) that he described have become familiar to many readers and are especially influential in the field of education. Gardner has distinguished the following intelligences:

- linguistic intelligence (abilities having to do with understanding and using the sounds, rhythms, and meanings of words and the functions of language)
- musical intelligence (abilities having to do with understanding and employing rhythm, pitch, timbre, and musical expressiveness)

[☆] *Change History*: December 2018. John Baer updated the text throughout the article.

This article is an update of J. Baer, Domains of Creativity, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 404–408.

- logical-mathematical intelligence (abilities having to do with finding logical and numerical patterns and producing chains of reasoning)
- spatial intelligence (abilities having to do with understanding the visual-spatial world and transformations within that world)
- bodily-kinesthetic intelligence (abilities having to do with control of one's body movements)
- interpersonal intelligence (abilities having to do with understanding and responding appropriately to the feelings, moods, and motivations of others)
- intra-personal intelligence (abilities having to do with understanding one's own feelings, moods, and motivations, with assessing accurately one's own strengths and weaknesses, and with drawing upon such knowledge to guide one's behavior)
- naturalist intelligence (abilities having to do with recognizing, categorizing, and drawing inferences about features of the environment; this intelligence was added later and was not part of the original list of seven intelligences)

Gardner's classification is based on such evidence as (a) the effects of brain trauma, such as strokes, that influence functioning in one domain but not others; (b) the existence of prodigies and autistic savants who show extreme abilities in one domain but not others; (c) psychometric evidence that suggests consistency among the skills that lie within a given domain and independence between the skills that fall in different domains; and (d) the existence of a set of core information-processing operations that can deal with specific kinds of input.

Gardner's eight intelligences are not the only way that domains have been conceptualized, but they will suffice as an illustration of the idea of broadly defined cognitive domains. The term domain is often also used to refer to general fields of knowledge or ways of knowing without specifying clear-cut boundaries between domains, and the breadth of what may be properly called a domain is in most instances not precisely defined. For example, a child's understanding of gravity may be viewed as a different domain of knowledge than her understanding of object permanence, number, animacy, and so on. It is also possible to lump many such understanding together as a single larger and more inclusive domain (in which case, for example, a child's understanding of gravity and her understanding of object permanence, number, animacy, etc., might be thought of as all falling within the domain of early mathematical and scientific concepts). Overall, as the idea that cognitive development is domain specific has increased in popularity among psychologists, the number of such domains has also tended to increase, and the breadth of the hypothesized domains has tended to shrink.

Some writers use the term microdomain to refer to subsets of skills that seem to go together and yet have somewhat separate developmental histories. The use of pronouns, for example, can be considered a microdomain within the larger linguistic domain, and counting skills can be thought of as a microdomain within the larger mathematical domain. There are not clear guidelines for demarcating domains and microdomains, and usages often overlap.

An important area of disagreement among those who argue for the significance of distinct domains of knowledge is the possibility of interaction among the skills and knowledge that make up the various cognitive domains. Some theorists argue for strict modularity; under such an interpretation, each information-processing module is encapsulated and cannot make use of representations from other modules. One oft-cited example of such an encapsulated module is the perceptual system, which is at least relatively immune from input from other modules (and thus one's beliefs or preferences cannot interfere, or can interfere at most only slightly, with what one sees or hears—and the fact that one does not want or expect to see an elephant in one's living room will in no way interfere with actually seeing or hearing an elephant if one should appear there!). Strict modularity is an extreme version of domain specificity, but modularity and information encapsulation are not essential features of theories of domain specificity.

Evidence for Domains of Creativity

Any evidence that there are different cognitive domains, even when that evidence is collected without consideration of levels of creativity, is indirect evidence that creativity is domain specific. This is true for the simple reason that creative performance must occur in *some* content domain; and if the basic cognitive skills underlying performance in that domain are domain specific, this will necessarily have an impact on creative performance in that domain as well as the performance of more ordinary tasks in the domain (tasks unrelated to creativity). And to some degree there is no dispute about domain specificity because everyone acknowledges at least some differences in the skills and knowledge one needs to perform or work or produce artifacts in different domains (e.g., no one questions that there are skills required in watercolor painting that are not needed in playing an oboe, and vice versa).

Questions about the domain specificity or domain generality of intelligence—which includes, for example, disagreements such as those raised by Gardner about the degree to which generic intellectual competencies exist and can be tested, as is assumed in standard IQ testing—are beyond the scope of this article, although they are clearly relevant because creativity requires competent performance as well as creative performance in a given domain. (They also provide a model for how to test the domain specificity/generality question in creativity, as discussed below.) The evidence for domain specificity of creativity goes beyond the assertion that different content domains rely on different basic skills for performance of all kinds, however. Even if there is a significant degree of general intellectual ability (or *g*, which is what IQ tests purport to measure) that influences performance across many domains, creativity may still be largely domain specific as long as *g* accounts for only a fraction of the observed differences in performance across domains. Domain specificity in creativity isn't an argument against (or for) general intellectual skills per se. What domain specificity theorists claim is that the skills, traits, and understandings that underlie *creative* performance—which are conceptualized as a set of skills, traits, and understandings that go beyond those skills needed for successful (but not necessarily creative) performance—vary from domain to domain. Under domain specificity, general intelligence might still influence performance across domains, but

creativity-specific skills or traits (such as divergent or associative thinking, resistance to premature closure, openness to experience, or intrinsic motivation) are not domain general skills of the kind that general intelligence (*g*) is theorized to be.

Arguments for the domain specificity of creativity are based primarily on research into the creativity of actual creative products, such as works of art, and not on the testing of specific intellectual abilities associated with various content domains. This evidence suggests that levels of creative performance on tasks in one domain are essentially unrelated to levels of creative performance on tasks in other domains, especially once the effects of *g* (as measured by IQ or similar general aptitude tests) have been statistically removed. This research has even shown that creativity in performing one kind of task within a broad cognitive domain may be unrelated to creativity in performing other tasks within the same domain.

A widely used technique in creativity research is to ask subjects to create something and then to have groups of experts in that field independently evaluate the creativity of those products. This method is called the Consensual Assessment Technique. It was developed and validated by Teresa Amabile (1996) in the early 1980s and has been used widely in creativity research since then. It is based on the idea that no matter what creativity may turn out to be and no matter what theory may someday best explain it, judgments of the creativity of work, products, or performances in a given field are most appropriately made by recognized experts in that field. Thus the creativity of poems is best judged by poets and poetry critics, and the creativity of cosmological theories is best judged by cosmologists. Although at the cutting edge of any field, places where paradigm-shifting work is likely to be the focus, there may be many disagreements about the creativity of a particular work or idea, assessments of more garden variety or everyday creativity—the kind of creativity that occurs in most psychological studies of creativity—tend to produce fairly uniform judgments among appropriate experts. Thus by asking a group of artists and art critics to independently evaluate the creativity of a group of collages, or a group of fiction writers and critics to independently evaluate the creativity of a group of stories, a researcher can obtain a reliable and valid measurement of the creativity of a group of creative products.

Many studies using subjects of different ages ranging from kindergarten to adults have shown that when subjects are asked to produce more than one creative product—such as collages, poems, stories, and mathematical puzzles—the creativity ratings of the products of each individual vary significantly. In fact, there is often little or no relationship between the creativity ratings a subject's various works of *different* types receive, despite the fact that the level of one's creative performance on a given task is highly predictive of performance on the *same* task, even when the second work is produced as much as a year after the first. For example, one especially large study examined the creative performance of participants in seven tasks, three art tasks and four creative writing tasks, allowing for multiple tests of domain specificity (including ones using combined art-mean and story-mean scores). The 16 within domain correlations were consistently large and statistically significant, as both domain generality and domain specificity theories would predict. Not one of 20 the cross-domain correlations reached the 0.05 level of statistical significance, however (Conti et al., 1996).

This approach to testing the domain generality/domain specificity question—looking for intercorrelations of performance scores across domains—is exactly the method used by psychologists to demonstrate the presence of general intellectual skills—*g*—when the Board of Scientific Affairs of the American Psychological Association (APA) established a Task Force to produce “an authoritative report” (Neisser et al., 1996, p. 77) on what is actually known about intelligence. The Task Force concluded that “subtests measuring different abilities tend to be positively correlated: people who score high on one such subtest are likely to be above average on others as well” and that psychometric evidence suggested “a hierarchy of factors with *g* at the apex” (p. 78). But when the very same approach has been used to look for domain generality of creativity, it has come up empty-handed. Unlike the results when testing for domain-general intelligence, the results in the area of creativity have consistently supported domain specificity.

It should be noted that this lack of relationship among creativity ratings on different products is not only true across broadly defined domains—such as the linguistic and artistic domains—but also, in at least some cases, within domains. A prime example of such within-domain task specificity is the lack of correlation between poetry- and story-writing creativity that has been observed in several studies.

Approaching the question of domain specificity of creativity from a creativity training perspective, it has also been shown that training in divergent thinking (which is the most common kind of creativity training exercise) can also be targeted to specific domains, or even to specific tasks within domains. For example, divergent thinking training using only poetry-relevant exercises—such as brainstorming words with similar beginning sounds (alliteration) or words that can stand for or represent a given thing or idea (metaphor)—tends to increase poetry-writing creativity but fails to increase story-writing creativity.

An important source of evidence *against* domain specificity of creativity—evidence favoring domain generality of creativity—comes from studies using self-report scales of creativity. When individuals are asked to rate their creativity across various domains, the levels of creative achievement they report in the various domains tend to be moderately correlated. Critics of this research point out (a) the questionable validity of self-report scales and (b) the response-set bias that may lead individuals to systematically under- or over-estimate their own creative activities in all or most domains.

Most tests of creativity assume domain generality — they are billed as tests of creativity, not tests of creativity *in Domain X* — but the most widely used such measure has, perhaps inadvertently, provided fairly strong evidence of domain specificity. The Torrance Tests of Creative Thinking, which purport to measure domain general creativity, were for many years the most widely used tests of creativity; in fact, in a 1984 study, Torrance and Presbury reported that the Torrance Tests accounted for three-quarters of all creativity research involving students and 40% of the smaller subset of all creativity research involving adults as subjects. There are two forms of the Torrance Tests — figural and verbal — and Torrance himself found these two forms of his test measured essentially different skills. “Responses to the verbal and figural forms of the TTCT are not only expressed in two different modalities... but they are also measures of different cognitive abilities. In fact, Torrance found very little correlation ($r = 0.06$) between performance on the verbal and figural tests” (Cramond et al., 2005, pp. 283–284). Kim (2017) has reported somewhat higher correlations between the two forms of the test in recent studies. The highest r of these studies was just 0.39, however, and others were

significantly lower. The corresponding estimates of shared variance between the figural and verbal forms of the Torrance Test in the four studies Kim cited thus ranged from less than one percent (which is also what Torrance found) to a high of 15% (this was the 0.39 study; $.39^2 = 0.15$). This suggests at most small amounts of overlap (domain generality) and large amounts of disjunction (domain specificity).

In 1998 the *Creativity Research Journal* published a Point-Counterpoint pair of articles debating the issue (Baer, 1998; Plucker, 1998) in which even the psychologist arguing for domain generality acknowledged that “Recent observers of the theoretical and empirical creativity literature could reasonably assume that the debate is settled in favor of content specificity” (Plucker, 1998, p. 179). Creativity theorists and researchers are far from unanimous about how best to interpret the available evidence regarding domain specificity of creativity, however, and although the trend in recent years has favored a much more domain specific approach, this could change depending on the results of future research.

It is interesting to note that the efforts to produce creativity in the area of artificial intelligence has also followed a very domain specific path. The earliest visions of artificial intelligence imagined robots that could speak and act much like humans — one leader, Herbert Simon, claimed in 1965 that “machines will be capable, within twenty years, of doing any work a man can do” (Crevier, 1993, p. 109). In fact, 20 years after making that prediction AI had largely shifted toward an expert systems approach, developing programs that answer questions and solve problems about very limited and specific domains of knowledge. Recent computer program success have included software with considerable levels of creativity, but almost always in very specific domains such as playing games like chess and Go, medical diagnosis, and musical composition (e.g., <http://artsites.ucsc.edu/faculty/cope/experiments.htm>). Domain general computer software has yielded little that observers might deem creative, but narrowly domain specific computer programs have produced creative accomplishments in many fields. This is not evidence that human creativity is necessarily domain specific, of course, but combined with research showing human creative performance tends to be strongly domain specific it does suggest that there may be something domain specific about the very nature of creativity, whatever its source.

Common Misunderstandings About Domain Specificity: The Puzzle of Polymaths

There have always been a few people of exceptional talent who are highly creative in multiple domains. Some observers focus on the rarity of such polymaths and take this as evidence in favor of domain specificity; others home in on the existence of polymaths, however rare they may be, and take it as evidence for domain generality. Either way, such arguments are misleading. Domain specificity does *not* predict there will be no polymaths; in fact, it predicts that some such multi-talented people should exist. And domain generality theorists can explain their rarity just as easily.

What domain specificity claims is that creativity in one domain does not predict creativity in other domains. It thus claims that correlations between creativity in different domains should, on average, be zero. This means that one should expect some people will have high levels of creativity in many areas and some should demonstrate very low levels of creativity in many areas, not that everyone should be creative in the same number of domains. Some creative painters might also be creative poets, while other creative painters might exhibit no creativity as painters whatsoever. (By way of analogy, think of any two unrelated traits, such as having green eyes and being tall. The fact that a few people with green eyes are also tall does not show these traits are related. When two factors are unconnected, they should be expected to appear together in some, but not most, cases. This is what randomness predicts.) If domain specific creative abilities are randomly distributed, one would *expect* a few people to be creative in many domains, some people to be creative in several domains, and some others to be creative in few domains or none, based on a normal distribution of unrelated abilities. The existence of a few polymaths does not disprove domain specificity. It is *exactly* what domain specificity predicts.

For very different reasons, the scarcity of polymaths can be explained by domain generality theorists, at least creativity at the highest, genius level. If creativity is domain general and a person has enough of it to be highly creative in any domain, then it might seem that one should be creative across the board. Most genius-level creators are *not* immensely creative outside the one domain in which they show excellence, however. This is probably best explained but what creativity researchers call the “ten-year rule,” which argues that it takes many years of preparation in a field before one can do ground-breaking work in that domain. If it takes ten years of hard work in a field before one can produce works of genius, it is hardly surprising that few people manage to reach the highest levels of creativity in a variety of fields. There simply isn’t time.

So the presence of creative polymaths tells us nothing about domain specificity, and their rarity tells us nothing about domain generality. In this case, both theories predict well the world as we find it.

Mixed and Hierarchical Models

Creativity theorists needn’t choose simply between domain generality and domain specificity. There are theories of creativity that incorporate aspects of both positions.

At the most basic level, one can simply posit the existence of both domain general and domain specific skills and traits. Amabile’s (1996) componential model, which argues for three factors—creativity general skills and knowledge, domain specific skills and knowledge, and task motivation—does just that.

Kaufman and Baer's (2005) (Baer and Kaufman, 2005) APT Model is a hierarchical theory of creativity that includes both domain general and domain specific elements. The central idea of a hierarchical model is that there are varying degrees of domain specificity and generality ranging from the most general, such as general intelligence (g), to the most specific (e.g., micro-domains or task specificity) There are four levels in the APT hierarchy:

- *Initial Requirements* are completely domain-general factors that influence creative performance to some degree across all domains (e.g., intelligence)
- *General Thematic Areas* are broadly defined fields or areas that include many related domains, such as Artistic/Verbal, Artistic/Visual, and Math/Science.
- *Domains* lie within larger General Thematic Areas and refer to more limited ranges of creative activities. For example, in the General Thematic Area of Artistic/Verbal one would find subdomains such as narrative fiction, drama, and poetry.
- *Micro-domains* refer to more specific tasks within domains. For example, within the domain of poetry one might find haiku, epic poetry, and sonnets.

A hierarchical model such as the APT provides a bridge connecting domain generality and domain specificity and argues that aspects of both theories should be not only acknowledged but incorporated fully into a complete theory of creativity.

Conclusions and Implications

If creativity is domain specific, it means that a single theory of creativity—such as the theory that divergent thinking is a basic component of all creative thinking—cannot account for the diversity of creativity across domains. Creativity theories must either become domain specific themselves or find some general approach to dealing with these domain-based differences. Similarly, domain specificity of creativity means that creativity testing as currently practiced is necessarily inadequate and of limited validity. And finally, creativity training programs cannot be assumed to increase creativity across all domains simply because they successfully promote creativity in one domain.

Baer (2010) has proposed a divergent thinking metatheory of creativity that, although encompassing all domains of creativity in a single conceptual scheme, nonetheless takes into account the domain specificity of creativity. According to this metatheory, divergent thinking is an important creative thinking skill, but the cognitive mechanisms underlying divergent thinking are different in each domain (or possibly even for each task within a given domain). Thus there are many *different* divergent thinking skills rather than a single divergent thinking skill. So, for example, divergent thinking skill in poetry would be associated with creativity in writing poetry, but not in creating collages, which would require an entirely different set of divergent thinking skills. Consider, by comparison, the thinking skill of “analysis.” Analyzing a sonnet, applied behavioral analysis, factor analysis, and analyzing tree rings might all require analysis, but in each case what we are calling “analysis” is entirely different. Divergent thinking as a general class of thinking skills is still a useful construct, however, both (a) because it makes this wide range of skills more coherent and easy to conceptualize and (b) because it makes it simpler to postulate and identify the appropriate domain specific divergent thinking skills that will be important within any given domain or microdomain. Thus in terms of what is happening inside a creative thinker's head, divergent thinking skill may actually be many unrelated, domain specific cognitive skills; but in terms of how psychologists can understand these many diverse skills (viewing divergent thinking from the outside, as it were), divergent thinking is a coherent class of skills that bear a strong family resemblance.

Moving from the implications of domain specificity for creativity theory to its implications for creativity testing, a domain specific understanding of creativity provides a very direct challenge to existing notions of how to test creativity. Simply put, to the extent that creativity is domain specific, creativity testing becomes that much more difficult. If creativity is domain specific, what exactly is one to test? Creativity testers will necessarily have to determine in which domain(s) of creativity they are interested, because under a domain specific theory of creativity, general creative thinking skill becomes an empty construct. Tests of creativity in specific content domains—which might use the Consensual Assessment Technique to evaluate the creativity of products, or might instead find simpler (perhaps paper-and-pencil) techniques for assessing domain specific skills—would still be possible in principle, but they could be of only limited range and applicability. Major test developers may not be willing to support extensive test development efforts for tests of such limited potential use.

Creativity training, on the other hand, can accommodate domain specificity of creativity rather easily. Most creativity training programs already use a wide variety of tasks, spread across various content domains, in the exercises they use to improve divergent thinking and other creative thinking skills. Creativity training programs aimed at a particular domain can easily limit their training exercises to ones connected to that domain, while programs aimed at increasing creativity in general—the vast majority of programs—must be careful not to limit their training exercises to just one or a few content domains.

Creativity theory has only recently begun to accommodate research evidence suggesting that creativity is task specific, although the hierarchical approach discussed above is promising. General, domain-transcending theories—if true—would have far greater power than domain specific theories that account only for creativity in a limited content domain. For this reason, and because creativity theories have historically been one-size-fits-all theories, domain general theories of creativity continue to have great appeal. Unfortunately, research suggests that creativity is domain general only to a very limited degree; for the most part, creativity appears to be domain specific.

It should be noted that the research evidence pointing toward domain specificity of creativity is fairly new, and, like the research that preceded it, this research may not tell the whole story. More research will be needed to clarify the conditions under which generality or specificity of creativity is the more valid perspective. In the meantime, both views will continue to claim adherents among researchers and theorists.

Glossary

Creative The term “creative” can be applied to any act, idea, or product that changes or transforms an existing domain of human endeavor. A phenomenon is creative if it is novel and, in some manner, useful or appropriate for the situation in which it occurs. This concept is sometimes called “Big C” creativity. Creativity in dreams, in drug states, and while concentrating would be examples of “Little C” creativity, which also refers to everyday creativity

Creativity The English word “creativity” is linked, historically and etymologically, with the Latin word *create*, to make, and the ecclesiastical Latin word *creator* (Creator). Both refer to the concept of origin (consider the related term “originality”). Some writers discuss the “Four Ps” of creativity: Person, Place (also called Press), Process, and Product

Dream Report A dream report is a person’s description of a recalled dream, typically reported in narrative form. The dream may be recalled spontaneously or elicited by someone else, as in a laboratory setting

Dream A dream is a series of images that occurs during sleep. They are usually visual and kinesthetic but may be auditory or even gustatory or olfactory in nature

Electroencephalogram (EEG) An EEG is a graphic description of the brain’s electrical potentials recorded by scalp electrodes and usually delineated by ink tracings as are the **electromyogram (EMG)** (graph of muscular changes) and the **electro-oculogram (EOG)** (graph of eye movements)

Hypnagogia It refers to characteristic mental activity as a person is falling asleep.

Hypnopompia It refers to characteristic mental activity as a person is waking up.

Lucid Dream Reports These are characterized by a person’s claims that he or she was aware that he or she was dreaming of the ongoing dream

Nightmares These are dream reports characterized by intense anxiety, confusion, terror, and/or other unpleasant emotions

Non-REM Sleep It is characterized by an absence of **Rapid Eye Movement (REMs)**. It occurs in each of the four sleep stages, namely Stage One Sleep, which occurs immediately after sleep begins, characterized by low amplitude and high frequency brain wave EEG tracings; Stage One Sleep, Stage Two Sleep, Stage Three Sleep, and Stage Four Sleep, which are characterized by progressively higher amplitude and lower frequency EEG tracings. REM activity is confined to the first two sleep stages

Rapid Eye Movement (REM) Activity It is characterized by rapidly occurring conjugate, synchronized horizontal or vertical eye movements during sleep and, to a lesser extent, during napping, daydreaming, hypnotic imagery, and similar times when a person’s attention is turned inward rather than toward the external environment

Sleep It is the recurring period of relative physical and psychological disengagement from one’s environment, characterized by cyclical stages

Sleep Terrors (also called Night Terrors) These are episodic conditions, usually occurring during Stage Four Sleep. They are characterized by unpleasant emotions and a lack of imagery. They occur developmentally, most often in childhood

Wakefulness This is the recurring period of relative physical and psychological engagement with one’s environment

Creativity, Dreams, and Culture

From the perspective of Western psychology, creative problem-solving is a process that can bring something new into being by someone (or group) who is aware of gaps in human knowledge, by identifying those limitations, searching for their solutions, and making guesses as to a potential resolution. This is followed by testing one's guesses (or hypotheses), producing something that fills the gap, and communicating the final product. Here we can see three of the "Four Ps" of creativity in action: Person, Process, and Product. The fourth P is Place, the culture in which creativity occurs, the culture that recognizes and supports the product, or the culture that rejects the product only to have its value be recognized in a later time and place. I would add a fifth P, Phenomenology – the subjective experience of the person engaged in creative work.

Dreams often play a vital role in creative problem-solving, helping to identify what is missing, searching for a solution, testing one's guesses, and formulating a product—a concept, object, or activity that meets human needs for survival, for enhanced work performance, for esthetic satisfaction, or for one's enjoyment. Examples would be a scientific discovery, a mathematical theorem, a philosophical insight, an artistic masterpiece, a military victory, or a diplomatic accomplishment. Creativity is a social construct, and the product's recognition by others depends on the culture in which it occurs.

Ullman, in 1965, listed four ways in which dreams can participate in the creative process. All dreams are original; no two are exactly alike. Dreams combine several images to form a novel narrative, one that is reported upon awakening (a process Freud called "secondary revision"). Dreams often contain images that are metaphors or symbols that convey the deeper meaning of those images. Hartmann (2012) adds that dreaming is more closely related to imagining than to perception, and is on the same continuum with a daydream, fantasy, reverie, or made-up story.

It is simplistic to call involuntary dreams "creative" because they do not intentionally create something. However, there are "lucid dreams" in which dreamers know that they are dreaming and make a creative effort.

Many indigenous cultures have appreciated the creative aspects of dreams. Among several Australian aboriginal tribes, it was believed that "The Laws of Dreaming" were laid down during what they call "The Creative Period." Each species has its own set of laws and all these laws, human and non-human alike, are part of "The Dreaming," the ground of all existence. From time to time, humans can obtain new information from "The Dreaming" and express it in songs, dances, and rituals. Hence, "The Dreaming" is dynamic, not static, in nature.

Shakespeare, in his play *The Tempest*, wrote about "such stuff as dreams are made on." He seemed to realize that dreams can mirror waking life, often using symbols and metaphors. Many dream images and activities directly represent the person or behavior in question. However, an image becomes a symbol when it has a deeper meaning, just as a dream activity becomes a metaphor when it conveys something not readily apparent. Freud (1900/1961) asserted that people dream in symbols and metaphors to guard themselves against unwelcome desires and drives. Adler (1958), one of Freud's contemporaries, broke with him on this issue, positing that dreams contain more positive than negative material. But both psychiatrists noted the continuity between dream life and wakefulness. This emphasis on dream/wakefulness continuity also can be found in the work of St. Thomas Aquinas, who wrote, "Those things that have occupied a man's thoughts while awake recur in his imagination while asleep."

This continuity is recognized by most contemporary dream researchers, such as Hall (1953), Domhoff (2018), and Foulkes (1985). The latter declared that dreams are meaningful but do not follow a preordained coded message that needs to be unveiled by a psychoanalyst. According to Foulkes, a dream is "knowledge-based" and is bound to reflect some of the ways in which the dreamer mentally represents his or her world. Foulkes continues to describe how almost anyone who is awakened from a dream is able "to identify some events as having rough parallels in her or his waking experience." There are many differences between waking cognition and dreaming cognition, but these differences are more continuous than discontinuous.

In 1979, Rycroft mused that if dreams are poetry, their efforts are imperfect. If they hope to have an audience, poets and artists cast their meaning in metaphors and symbols that are part of their culture's shared legacy. On the one hand, most dream imagery in contemporary Western cultures tends to be too dependent on the dreamer's personal experiences to have wide appeal. For example, dreams are sometimes turned into stories or movies during psychotherapy (Jenkins, 2012). However, dreams sometimes provide raw material for literature, as attested to by Robert Louis Stevenson, Steven King, William Styron, Amy Tam, and others (Ruprecht, 2007).

It should also be noted that many indigenous cultures have formulated their own repository of symbols and metaphors so that an elder can help a young dreamer fathom a dream's meaning (e.g., Lohmann, 2007). However, some pre-Columbian tribes held that a dream's meaning was dependent on the dreamer's personal concerns. There were tribes that stressed the problem-solving function of dreams, while other tribes saw them as forecasting future events. Some Native American cultures believed that dreams portrayed directions for the dreamer, while others thought that dreams depicted events in the spirit world. For some tribes, dreams about sex revealed "the secret desires of the soul," resembling Freud's concept of "wish fulfillment."

Among the Quechua of Peru, maize is a symbol for money, and potatoes for livestock. If someone dreamed that a stranger was asking to exchange potatoes for maize, the dreamer might check the safety of his cattle, suspecting that a rustler might be in the neighborhood. Among the Toraja of Indonesia, personal dream symbols are common, as this is a society that grants considerable personal authority to its members. As a result, there may be disagreements about a dream's meaning, and a discussion is needed to reach a resolution. The Toraja frequently assign meanings to dreams based on reversals; if a person of high status has a nightmare, this is seen as a confirmation of the dreamer's authority.

All these indigenous perspectives stand in sharp contrast to Crick and Mitchison's 1983 proposal that dreams function to purge unnecessary, even parasitic, brain cell connections produced during wakefulness. Thus, dream content is best off forgotten. But

other dream researchers agree with Hobson (1988) that dream images are random and accidental. Even so, the ability of the sleeping brain to work those images into a coherent story stands as a testimony to the universality of esthetic experience. In dreams, he noted, everyone can become a writer, a painter, or a film-maker, combining extraordinary sets of characters, actions, and locations into strangely coherent experiences. In 1988, he wrote "I strongly object to any implication that the artistic experiences of waking or dreaming are fundamentally pathological, defensive, or neurotic The brain is so determined to find meaning that it creates dreams out of images that have been randomly evoked by its own neurochemical activity."

Research on Creativity and Dreams

Weisberg, in 2006, stated that creative problem-solving has occurred when a person produces a novel response that solves a problem at hand. He went on to debunk some highly publicized examples of creativity in dreams and other alterations in consciousness. A critical perspective needs to be taken regarding not only anecdotal accounts but also structured research programs. Creativity in dreams is a phenomenon that is difficult to investigate for several reasons. A researcher does not work with dreams but with dream reports. These reports, whether obtained from archives, from field research, or from a sleep laboratory, are subject to vagaries of memory, unconscious (or deliberate) distortion and elaboration, and semantic issues (the researcher and the participant may differ on the meaning they attribute to key words). Researchers in this area need to maintain a sense of modesty when announcing the results of their work.

Anecdotal Data. Keeping Weisberg's caveat in mind, many reports of creativity in dreams have not been challenged. They include Howe's invention of the lock-stitch sewing machine, Blake's development of a copper engraving process that he later used to illustrate his songs, Tartini's composition of his most celebrated sonata, and fictional work by Robert Louis Stevenson and Daphne du Maurier, among others. The mathematician Jerome Cardan credited a recurring dream for his most widely read work, *De Subtilitate Rerum*. Whenever Cardan became lax in his writing habits, his dream would return with great force. Carl Jung's creative approach to the study of dreams was acknowledged for decades, but his artistic creativity was not apparent until the posthumous publication of *The Red Book*, in which he illustrated his dreams and other manifestations of his inner life.

Some contemporary writers credit their dreams with characters and plot developments (e.g., Almansi and Begun, 1986). Stephen King revealed that he used one of his own nightmares in one of his novels. Isabel Allende was inspired to write *The House of Spirits* by her dreams. However, she was unable to bring the novel to a satisfactory conclusion until she had a dream about her grandfather that produced a perfect ending. William Styron was working on other projects when he dreamed about a young woman who had been an acquaintance several years earlier. Her charisma in the dream was so powerful that Styron dropped all other work to focus on writing *Sophie's Choice*, one of his most successful novels and one in which the central character's struggles had little to do with the woman who inspired the dream (Rupprecht, 2007). Two well-known "beat" writers, W.S. Burroughs (1995) and Jack Kerouac (1971), wrote books based on collections of their dreams.

In 2017, Webb produced a compendium of several dozen popular songs that originated in dreams. Among them was Paul McCartney's "Yesterday," the most re-recorded song of modern times. The melody was so complex that McCartney initially thought that he had copied someone else's work. Barry Manilow claimed that dreamed about his song "One Voice" in complete form. Sting shared that the title of "Every Breath You Take" originated in a dream; waking up, he finished the song in half an hour. On the other hand, Johnny Cash said that his song "The Man Comes Around" originated in a dream about Queen Elizabeth II. Billy Joel once stated, "I dream music all the time"; his dream-inspired album "The Stranger" won a Grammy for the Album of the Year.

In a discussion about his dreams, Sting provided an intriguing account of his creative process while composing songs for his album "The Wild Wild Sea. A song may begin as "disjointed fragments recalled from a night of fitful sleep." He turned the dream vignettes into song, often re-entering "that realm that is halfway between sleep and waking." Dream researchers call this realm "hypnagogia" if it occurs while one is falling asleep and "hypnopompia" if it occurs when one is awakening. Mary Shelley attributed her novel *Frankenstein* to hypnagogic images she had after her host challenged his guests to produce a ghost story. Mary Shelley won the contest and eternal fame.

Many creativity researchers use a framework of preparation, incubation, inspiration, and verification in their analysis of anecdotal reports. Creativity, of course, may not follow such a linear progression, but when it does, a dream might provide the inspiration following a period of conscious and unconscious incubation. Often, one's deliberate attempts to solve a problem might be fruitless, but these efforts are abandoned during sleep. Dreams can impart clues and novel approaches that have been elusive during wakefulness. It may be the case that similar results could occur simply by taking a break. Incubation still might be taking place until the sudden (or gradual) inspirational insight occurs. Mary Shelley's preparation for her famous novel occurred long before she knew about the contest; she was familiar with the "Gothic" takes of that era. Once the contest was announced, it was likely that she unconsciously began to pull together an engaging narrative. Inspiration resulted in her hypnagogic images, and winning the contest was the verification of her narrative.

Formal Research Data. Several investigators have used tests, questionnaires, and interviews to obtain information about creative problem-solving in dreams. An experiment reported by Brodsky, Esquerre, and Jackson in 1991 asked participants, while they were awake, to apply an operational definition of dreaming to four problem-solving tasks. All proposed solutions were rated on a five-point scale by raters, working independently. No gender differences were noted nor was frequency of recalled dreams associated with the creativity ratings. However, participants who attributed considerable importance to their dreams received higher creativity

scores, as did participants who reported having had lucid dreams. The researchers suggested that dreaming is a “permission-giving” format for eliciting active imagination, bypassing typical goal-oriented cognitive processing.

A series of experiments reported by Cartwright (2010) demonstrated that problem-solving in dreams is more successful when the material to be processed is either emotionally relevant or personally meaningful. Hartmann (1991) found that people with “thin boundaries” (a personality trait) are more likely to have nightmares and to be associated with the arts. A questionnaire study of college students conducted by Hartmann found that art majors reported the most nightmares, while physical education majors reported the fewest. Students who had frequent nightmares had more visual imagery upon awakening, became easily absorbed in aesthetic stimuli, and demonstrated high hypnotizability.

In 1970, Hall and Lind used the content analysis method to study the writer Franz Kafka’s 37 recorded dreams. They found personality traits consistent with what is known about Kafka, demonstrating the “continuity between dreams and waking life.” Hall and Van de Castle (1966) had developed content analysis after collecting some five thousand dreams and noting the frequency of common dream images. Music or sound appeared in only 1.5% of those dreams. So, it is quite remarkable that so many composers, both classical and popular, found a link between their dreams and their work. Richard Wagner not only received inspiration for his operas from dreams but even had his own dream theories. Some of them involved what Freud was later to refer to as “condensation,” in which a dream can incorporate several elements. Beethoven, Schubert, Schumann, Brahms, Berlioz, Bruckner, and Stravinsky all credited some of their compositions to dreams (Webb, 2017).

Possible Mechanisms

Contemporary sleep and dream research has demonstrated the elaborate, intrinsic mechanisms of “state” control. In other words, a change in the brain’s state while asleep changes the dreamer’s phenomenology. Sensory input can be internally controlled so that even the transforming mechanisms do not operate alone to protect the system from overload. Three features of contemporary conception of the nervous system – its intrinsic plasticity, its auto-regulation, and its creativity – provide a very different set of operating principles upon which to construct a scientific psychology of sleep and dreaming. This perspective proposes a nervous system that can turn itself on and off, regulate the flow of internal information in diverse ways, and control external information’s access to the system. It is in the context of this model that the incorporation of pre-sleep stimuli, dream incubation, and lucid dreaming assumes importance for the understanding of creativity and dreams.

Incorporation of Pre-sleep Stimuli

The influence of pre-sleep stimuli in dream content has been successfully demonstrated in experiments using hypnosis, subliminal stimulation, emotionally arousing films, and real-life stress situations. The results indicate that it is relatively easy to influence dream content in predictable ways. For example, Cartwright (2010) found that reaction to pre-sleep stimulation (such as that provided by erotic films) elicited dreams that provided emotional support for the dreamer’s reaction to the stimuli. Dreams may assimilate emotionally arousing information into problem-solving solutions that are already embodied in existing memory systems.

Dream Incubation

Serapis was the Egyptian god of dreams, and several temples were devoted to his worship, some of them dating back to 3000 BCE. In ancient Greece, over 400 temples were dedicated to Aesculapius, the god of healing and the intermediary of dream incubation. A citizen was not allowed to drink alcoholic beverages for three days before entering a dream temple, because it was believed that useful dreams were unlikely to occur while the dreamer was under the influence of alcohol (a sentiment that is backed up by research demonstrating that alcohol drastically reduces REM sleep).

Dream incubation was common among the American Plains Indians. Upon entering adolescence, an Indian boy would retire to a solitary location, incubating a dream about the identification of his guardian spirit or totem animal. An eagle or bear was often interpreted as the sign of becoming a future warrior, a wolf of becoming a successful hunter, a serpent of becoming a future medicine man. However, different tribes attributed different meanings to the appearance of these creatures in dreams. In ancient China there was a tradition of dream incubation among artists. For example, in the ninth century, Kwan Hiu regularly engaged in a ritual of prayer to a holy person before falling asleep. He was rewarded by a dream of the saint, awakened with the dream image in mind, and proceeded to paint it.

The neurologist W. B. Cannon stated that he had rarely gone to bed preoccupied by a problem without the solution being in his grasp when he woke up the next morning. The mathematician and philosopher Bertrand Russell would often work on an abstract mathematical problem to the point of exhaustion, and then go to sleep. He claimed that the answer to his problem would frequently occur in a dream. The artist Giorgio de Chirico referred to his dreams as a “source of inspiration” and advised “constant control of ... all the images that present themselves to our minds.” The surrealist Salvador Dali also claimed to have had a remarkable ability to induce and utilize his dreams, as did William Blake and Paul Klee (Barrett, 2001).

Foulkes (1985) moved from the anecdotal level to more rigorous types of inquiry, teaching 23 participants “dream control” methods, and asking them to dream about randomly selected topics. The participants kept daily records of their dreams for 10 nights. Judges attempted to match dreams with the suggested targets, but their matchings did not exceed what would have been expected by chance. The same investigators designed a second study using 29 highly motivated participants who claimed some previous success in dream control or an interest in the topic. They spent 10 nights attempting to dream about assigned topics, but once again, judges were unable to match the dreams with the topics.

However, Reed and Van De Castle have reported more encouraging results in projects in which incubated dreams focused on real-life concerns, not on abstract topics, but on real-life concerns (Van de Castle, 1994). Barrett (2001), Delaney (1990), and Garfield (1974), all former presidents of the International Association for the Study of Dreams, have cited case reports indicating how dreams can help many people live more fully integrated lives and augment their capacity for adaptation and personal growth.

Lucid Dreaming

When dreamers realize that they are dreaming, the dream is called “lucid.” The Tibetan Buddhist practice of “dream yoga” focused on the ability to remain aware and lucid during nighttime dreaming. However, the Hindu yogic dream tradition eschewed such dream manipulation in favor of a waking meditation practice described as “merging with the light.” Aristotle wrote about dreams in which “the sleeper perceives that he is asleep and is conscious of the sleeping state during which the perception comes before his mind.” In the second edition of *The Interpretation of Dreams*, published in 1909, Freud noted that some people are clearly aware when they are dreaming, and can direct their dreams.

Firsthand reports from lucid dreamers have produced several methods thought to be useful in facilitating the experience. Asking such critical questions as “Is this a dream?” and “Am I dreaming?” during a dream will often produce lucidity. Some dream workers encourage people to ask these questions during the day at regular intervals, with the expectation that these questions will later arise during the night. Specific skills are sometimes learned in lucid dreams. Jack Nicklaus, after winning several golf championships, found himself in a slump. He regained his form after learning a new golf stroke in a lucid dream. Researchers estimate that half the population of the United States experience a lucid dream at least once, while one in five report HAVING one each month. Lucid dreaming has been used therapeutically, especially to help people suffering from repetitive nightmares (Krippner et al., 2002).

Neurophysiological and Neurochemical Mechanisms

Several studies with non-human animals indicate that the amount of time spent in REM sleep increases as a result of new learning, such as finding the way out of a maze. This relationship is evident in work conducted with cats, mice, rats, and newly hatched chicks. Therefore, REM sleep may play an important role in the consolidation of such cognitive activities as learning, memory, and problem-solving for both humans and other organisms that engage in REM sleep. New protein structures are synthesized in the brain during REM sleep and could well be the forerunners of creative change in how dreamers view themselves and their world. The evidence indicates that the initiation of REM sleep comes from the brainstem, then extends itself over the entire brain cortex.

Some theorists have used computer analogies to describe REM functioning as akin to “off-line processing” in computer science. The acquisition of input information is temporarily stored in computer-like memory until processing components are available. Information about the day’s events is gathered and stored until the onset of REM sleep when it can be “processed,” integrated with memories, and formed into strategies for the future. It is hypothesized that EEG theta rhythms associated with hippocampus activity during REM sleep signals that information processing and future planning are taking place.

The spiny anteater, or echidna, is an early mammal whose sleep pattern shows no REM activity. The echidna’s brain, however, has a large prefrontal cortex, presumably to integrate new experience with older experience. The mammals that evolved later were able to handle this task more efficiently during REM sleep; as a result, their brains were smaller – a more efficient direction for evolution to follow. This problem did not exist in the earlier reptilian species; their behavior was largely reflexive, and this activity was adequately handled by a small brain with a neocortex. Dreams, then, can serve as a window on the neural processes whereby – from early childhood on – strategies for behavior are being set down, modified, or consulted. This process and the mechanisms involved were termed the “unconscious” by Freud and can be used advantageously in the clinical setting by both Freudian and non-Freudian psychotherapists and other dream workers.

Hobson proposed that cells deep in the pontine area of the brain stem are periodically activated during sleep, generating REM sleep and randomly stimulating the forebrain, which then synthesizes dreams by using stored memories to make sense of the incoming neural firing. On the one hand, Hobson reduces dreaming to biochemical events in the brain, but on the other hand, he has a keen understanding of dreams as imaginative creative events.

Hobson points out that Freud insisted that wishes and repressed desires caused dreaming but that this notion has been discredited due to data that brainstem mechanisms during sleep cause dreaming. Once these mechanisms trigger REM sleep (and dreaming), wishes may be expressed and may even shape dream plots, but they are in no sense causative of the dream process.

Hobson's model proposes that during both waking and dreaming there is an activation of the brain, an information source that is evoked, and a biochemical modulation that differs radically from wakefulness to sleep. Dream experiences, in part, are a product of the brain's self-organization during which the randomly evoked information is patterned into a narrative to which meaning can be attributed. The cells in the brain's pontine area are activated, generating REM sleep and stimulating the forebrain, which then makes sense of the results of the neural firing. Like other subjective experience, dream material tends to be organized by the linguistic faculty of the brain. Thus, Hobson concludes that dreams are not the result of an attempt to disguise repressed wishes but are a direct expression of a synthetic effort. Even though Hobson disagreed with Freud regarding the origin of dreams, he concurred that dreams are the "royal road" to a scientific understanding of consciousness.

Hobson's model is seen as unduly reductionist by those researchers who hold that REM sleep and dreaming are two separate processes. Foulkes has presented laboratory data indicating that considerable mental activity occurs outside of REM sleep, even though the quality of non-REM mentation is quite different. Non-REM dreams also play a role in memory consolidation, but mainly for recent events. Krippner and Combs (2002) have noted that in both REM and non-REM dreams the formal analysis of activity patterns in complex neural networks can be carried out in terms of chaotic attractors. They proposed that the dreaming brain "relaxes" into patterns of self-organized neural activity that often reflect the residual moods, stresses, and concerns of everyday life. In the creative process, small changes in cognition or behavior can trigger an avalanche of novel creative products. This "butterfly effect" characterizes many dreams that lead to a creative solution to an ongoing program. Krippner and Combs agree with Hobson that the brain's self-organization capacity is apparent in dreams but suspect that there is a data bank of "personal myths" that is utilized in the resulting narrative.

Cartwright (2010) adds that the dreaming process has a remarkable access to memories and emotions. Dreams are not constrained by the realities of waking life, thus allowing mental processes to work unhindered with these materials, to experiment, and to create until answers arrive. But problem-solving in dreams is not limited to mechanical, scientific, or artistic participants. Even more common are dreams that help with emotional dilemmas. Cartwright and Lamberg, in 1992, drew upon the dream research literature to propose ways in which psychotherapists, counselors, and dreamers themselves could recall and utilize dreams to overcome depression and anxiety brought about by divorce, bereavement, serious illness, and job loss. In fact, the very process of dreaming about such difficulties seems to be a creative remedy for the dreamer's emotional pressures.

Further Research

Arieti (1958) cogently stated a critical issue underlying the relationship between dreams and creativity, proposing that dreams are often original, but they are not fully creative. For dreamers, the impact of the customary environment is removed, and the dreamer places few if any restraints on dream content. Unexpected connections occur. Some combinations of scenes and events take place that have never occurred either in nature or in the dreams of other people. But the same can be said of some schizophrenic ideation! However, the schizophrenic is unprepared to utilize original, unusual, and bizarre ideation in crafting creative products. And sometimes, a dream can be extraordinarily complex; Arieti reports the case of Antonio Ludovico Muratori, an 18th century scholar, who dreamed about composing a Latin verse, a pentameter that ordinarily would require complex use of metric technique. But, to Arieti, this is the exception that proves the rule; for him, it is important to distinguish between originality, "ordinary creativity" (what Richards has called "everyday creativity"), and "great creativity" which may have a great impact upon the future of human society.

The field of dream research is extraordinarily rich, connecting to several other disciplines. Future research studies need to identify the genetic markers for creative behavior, reconcile personality and cognitive research data in creativity, evaluate the part played by the dreaming process in creative ideation, determine the role of mental illness in blocking or facilitating creative expression, and specify what home and school variables are key factors in the development of highly creative individuals.

It is apparent that individual differences exist in dream creativity, and that there are cultural differences as well. The vast preponderance of studies in the field are devoted to the neurophysiology and neurochemistry of sleep and dreaming as opposed to the psychosocial variables in dreaming, and, of the latter, only a handful concern themselves with creative aspects of dreaming despite the near-consensus of dream researchers that the two phenomena are linked in several ways.

The unanswered questions posed by existing research data are legion, for example, why is color spontaneously reported in the dreams of half of art students studied, 16% of the science majors, and virtually none of the engineering students? Why do subjects, in general, tend to report color in their dreams more frequently if they claim to place greater reliance on feelings than on thinking? In laboratory studies, why does recall of color in dreams disappear quickly if the investigator does not ask for it? What is the nature of dreams in which color is greatly intensified, radiating with phosphorescent hues? What is the nature of dreams that a dreamer who almost always dreams in color swears have occurred in black and white? What are the mechanisms that determine shifts in dream color when people wear colored goggles during every waking moment for a week? Why do members of some cultural and social groups report more and different colors in dreams than do others? Why do children report more color in dreams than adults?

The answers to these questions can be sought from psychosocial, neurophysiological, neurochemical, and phenomenological investigations, as can answers to dozens of additional questions relating to creativity in dreams. In the meantime, for the Australian aborigines, the Amazon Kagwahiv, and other tribal people, the "Dreamtime" and "The Dreaming" still exist. They believe that if

other human beings would begin to make their own dream journeys, reestablish their links with Nature, and creatively invoke Dreamtime songs and dances, many of the world's current dichotomies and discontinuities could become accommodated and transcended. For both the mind/brain and the individual/group, this has been one of dreams' creative functions over the millennia. The need for creative solutions to the world's many social, economic, and environmental problems reflects the importance of creativity, and of the researchers and dream workers who see creativity in dreams as a critical frontier in understanding and assisting human development in a world – and a species – currently at risk.

Introduction

Many stories, both positive and negative, are in the popular culture regarding the relationship between drugs and creativity. But what is the reality? Do drugs enhance or deter creativity? This entry will review some historical literature regarding creativity and the use of a variety of drugs including cannabis and hashish, cocaine, Lysergic Acid Diethylamide (LSD), opium, psilocin, and psilocybin. Then the research regarding creativity and these drugs will be reviewed. Finally, the relationship between creativity and prescription drugs will be discussed.

Drug Use and Research

Opium was used by doctors in Greece in 100 BC. In North America, drug use dates back to native tribes in the United States and Mexico who took mushrooms and peyote within the context of religious ceremonies. Coca leaves were used by natives as a part of social life, work, and worship for thousands of years in South America. These drugs were a part of the cultural fabric and have a genuine spiritual connotation for many practitioners.

Traditional and newer man-made prescription drugs have contributed to a situation where substance dependence and abuse have become widespread. The United Nations Office of Crime and Drugs The World Drug Report (2018) stated that globally 275 million people (5.6%) used drugs in 2016 and 31 million suffered enough harm that they needed treatment. Drug and alcohol use trends downward as people get older but for addicts use can increase as more of the substance is needed to generate a high.

Concrete statistics on drug use among creative people is scant. Anecdotal evidence based on public disclosure indicates it is above the norm, but objective studies that delineate the relationship between creativity and drugs are difficult because it varies so much by individual and many eminent creative people are understandably reluctant to discuss it publicly.

Nevertheless it is clear that some creative professions participate in drug subcultures which vary according to the type of drug. Radenkova-Saeva (2008) defined drug subcultures as “groups of people loosely united by a common understanding of the meaning and value (good or otherwise) of the incorporation into life of the drug in question” (p. 22). These groups often form friendships that involve taking “the drug together, possibly obeying certain rules of etiquette, to full-scale political movements for the reform of drug laws. The sum of these parts can be considered an individual drug’s culture” (p. 22).

Examples of psychedelic art in a variety of domains will be discussed below. According to Krippner (2017), “psychedelic art” is not defined by its content but by a certain type of experience (or experiences) that have affected and impacted the artist. These experiences were evoked by substances variously called “psychedelic” (“mind-manifesting”), “entheogenic” (“evoking the divine within”), “hallucinogenic,” or even “psychotomimetic” (“among others”) (p. 416). Krippner (2017) interviewed 189 artists and writers in a study regarding the use of psychedelics in the late 1960’s and early 70’s. He found that taking the drugs influenced the content, approach, and technique of their work. For musicians drug use influenced lyrics, texture, and mood.

Cannabis and Hashish

Cannabis (also known as marijuana, weed, pot, etc.), are the buds and leaves of the Indian hemp plant. THC is a psychoactive chemical found in the plant which causes relaxation and reduced short-term memory. Continued use may result in increased anxiety and paranoia in some individuals.

Cannabis is a milder form of intoxicant than hashish which is a hardened form of cannabis that is eight times stronger. Cannabis was used as early as 3000 BC in Egypt and was used up until the 20th century before it was made illegal in most countries. Presently there are some countries where cannabis is legal, including Canada, The Netherlands, Spain, etc. In some countries, it is illegal but the law is not enforced and in other countries the use of medical marijuana is permitted. The United States is moving toward legalization with 15 states where it is legal in 2020.

Louis Armstrong started smoking in the 1920s and used it all his life on a daily basis. He even planned to write a book about it called *Gage* but his manager thought it was a bad idea and the manuscript was put away. Armstrong was arrested once for possession but never went to jail. Actor Robert Mitchum was not as lucky—he spent two months in the Los Angeles county jail for possession.

In the 1960s and 1970s marijuana became a commonly used drug as it still is today. The pot subculture includes hundreds of pop songs that praise grass. Stoner movies became a minor genre which included *Up in Smoke* starring Cheech and Chong, *Pineapple Express* and *Harold and Kumar go to White Castle*. Sean Penn became a star playing a stoner in *Fast Times at Ridgemont High*.

While in the 90's Bill Clinton claimed he never inhaled, Barack Obama felt free to mention he smoked grass in his autobiography. Richard Branson, the Chairman of Virgin Airlines and Presidential candidate Michael Bloomberg of New York also publicly disclosed they had used grass. Some creative individuals such as comic Bill Maher and Willie Nelson became elder statesmen of pot publicly discussing the fact that they smoked cannabis regularly although Nelson recently announced he was stopping his use for health reasons.

Opium and Heroin

Perhaps the oldest drug is opium which is produced using seeds from the opium poppy. Opiates include opium, morphine, and heroin which work on the brain and spinal cord lessening pain and creating a feeling of euphoria. Smoking opium did not come into vogue until the discovery of Indians smoking tobacco.

Symphony Fantastique by Hector Berlioz is an example of a classic work inspired by his opium use. The story is based on Berlioz's unrequited love for an Irish actress named Henrietta Smithson. Movements 4 and 5 occur after a young musician poisons himself in despair and experiences strange visions which are translated into his music. Smithson had left for London when Berlioz wrote the symphony but by the time it was performed she returned to Paris and attended it's opening by chance. Berlioz ended up captivating her heart and marrying her but sadly the marriage did not work out.

Charles Baudelaire, the French poet, and Alexander Dumas belonged to The Club des Hashischins where hashish was taken every month at séances. Baudelaire clearly had addiction problems with alcohol and opium as well as hashish that may have contributed to his death. Coleridge is alleged to have written the *Kubla Kahn* under the influence of opium. Other famous opium users include Elizabeth Barrett Browning, Sir Walter Scott, and W. B. Yeats.

Escaping from the confines of life was used as an explanation for his opium use by Cocteau. Baudelaire wrote:

Opium magnifies that which is limitless
Lengthens the unlimited
Makes time deeper, hollows out voluptuousness
And with dark, gloomy pleasure
Fills the soul beyond capacity

Quoted in Largo, 2008: 24

By the 20th century stronger forms of opium including heroin had been concocted. A heroin subculture became prevalent in the jazz community from the 1930s to the 1960s. Talented musicians such as Billie Holliday, Charlie "Bird" Parker, and Chet Baker's deaths were related to heroin. Others such as Miles Davis whose album *Birth of The Cool* is considered the best in history by many as well as Ray Charles also used heroin. Rock stars Janis Joplin, Jim Morrison, and Kurt Cobain died from heroin or morphine overdoses along with many others. Comics Lenny Bruce, John Belushi, and John Candy also died of drug overdoses. Lenny Bruce said: "I'll die young but, it's like kissing God." Movie biographies of musicians who became hooked on some type of drug have become a genre.

Cocaine

Cocaine is a concentrated form of coca leaves which is usually snorted and absorbed quickly. It creates a very intense high. Eventually cocaine addiction can lead to severe problems in the nasal cavity, along with paranoia and insomnia.

Sigmund Freud wrote a paper called *Uber Cola* in which he experimented on himself a *dozen times* and noted the “exhilaration and lasting euphoria.” He later changed his mind about benefits when a friend died from an overdose. Other prominent creative individuals who used cocaine include Elton John, Stevie Nicks, and Isadora Duncan.

Dr Jekyll and Mr. Hyde is thought to be at least subconsciously about drug use and personality change. Robert Louis Stevenson was a cocaine addict who allegedly wrote the book while using. Sir Arthur Conan Doyle depicted the destructive aspects of cocaine in Sherlock Holmes who became addicted. Nelson Algren’s *Man with The Golden Arm* about a morphine addict won the National Book Award and was made into a movie starring Frank Sinatra.

Lysergic Acid Diethylamide (LSD)

Albert Hoffman, a research chemist, had a hunch that lysergic acid diethylamide (LSD) might have some special properties in 1943. In his book, *LSD: My Problem Child*, he described what happened when he was preparing some concentrated LSD for the first time. He suddenly became dizzy and felt he had to go home and lie down. In the next two hours he experienced intense colors, fantastic pictures and a pleasant intoxication. Hoffman knew he was on to something special and likened his recognition to Louis Pasteur who said, “luck only happens to those who are prepared.”

Hoffman’s experience inspired interest into researching the power of LSD by psychiatrists working with schizophrenia, alcoholism, and patients in therapy. Oscar Janiger completed an 8½ year study in Los Angeles which ended in 1962. He eventually recruited 930 individuals; initially half were in psychotherapy and half were in the general population. So many professional artists volunteered that he added a substudy. Janiger discovered artists “somehow found a way to harness the LSD state to the creation of art and were able to increasingly control the physical expression of their subjective experiences” (de Rios and Janiger, 2003, p. 24). According to de Rios and Janiger: “The heightened aesthetic sensibilities of the psychedelic experience clearly broaden the individual’s subjective sensitivities. In the great majority of reports we see instances in which moral values were affirmed, emotional conflicts were resolved, and participants appear to have been better able to cope with human predicaments” (p. 42).

There was also a strong spiritual component—24% of participants experienced “a mystical or spiritual encounter” (p. 115). No negative effects were reported. One of the subjects, movie star Clark Gable, talked openly about how he had a psychological breakthrough with the help of LSD. Later another movie star, Cary Grant, spoke about how taking LSD under a therapist’s supervision was a positive turning point in his life.

In 1963 LSD moved out of the lab and into the popular culture with a huge splash as Timothy Leary and Richard Alpert were thrown out of Harvard for advocating LSD use for everybody. By 1965 it was illegal in California but the genie was out of the bottle. Acid helped inspire the hippie movement which began with the summer of love in San Francisco and continues in spirit today at the Burning Man festival.

John Lennon and Paul McCartney were initially reluctant to discuss having taken acid but later stated that Beatles songs inspired by acid included *Lucy in The Sky with Diamonds*, *Magical Mystery Tour* and *Day Tripper*. Other groups contributed to a genre called psychedelic rock which included some of the biggest stars of the time including The Grateful Dead, The Jimi Hendrix Experience, Pink Floyd, and Jefferson Airplane. Jim Morrison named his band The Doors after the *The Doors of Perception*, Aldous Huxley’s book about mescaline. Brian Wilson of the Beach Boys took LSD which probably influenced *Good Vibrations*.

Ken Kesey toured the country in a colorful old bus taking acid which helped inspire *One Flew Over The Cuckoo’s Nest*. The film won 5 Academy Awards including best actor for Jack Nicholson, who had his own personal experience with LSD which inspired the writing of a movie entitled *The Trip*. Tom Wolfe wrote the best seller *The Electric Kool-Aid Acid Test* about Kesey.

Among other notable individuals who said LSD had an important influence on their life was Steve Jobs, the most creative executive of his time and Steve Wozniak, his partner who designed the first Apple computer. Scientists include Kary Mullins, a biochemist who claimed that taking LSD helped him recognize the polymerase chain reaction in DNA which won him the Nobel Prize and Sir Francis Crick “who told several friends that the double helix of DNA came to him in an LSD session” (Krippner, 2017, p. 428).

Psilocin and Psilocybin and Ayahuasca

Initially used by the Aztec Indians, “magic mushrooms” became popular during the 60’s. However they were used as part of traditional spiritual ceremonies dating back to 1500 BC: “In Mexico and Central America, stone sculptures...portray mushrooms from whose stems emerge the heads of deities” (Krippner, 2017, 57).

Ayahuasca, a tea made from the *Banisteriopsis caapi* and *Psychotria viridis* plants, was also used by Indians in Brazil in religious ceremonies. Like LSD, some individuals who took hallucinogenic mushrooms and ayahuasca reported having mystical experiences that significantly improved their lives, including their creativity.

A Summary of the Research

A simple summary listing the definitive results of drug use and creativity would ideally be presented here; however the research simply isn’t that conclusive yet. For example, in studies on cannabis In 2018, Iszai and his colleagues conducted semi-structured

interviews with 72 artists about the use of cannabis and alcohol in their work and for pleasure. They “found that for some artists, substance use is not only characteristic to creation, but it is also part of their everyday lives.” (p. 1275) The artists felt that alcohol and cannabis helped their creative process. However, a randomized double-blind study by Kowal and his associates in 2015 indicated that participants who took lower doses of cannabis didn’t experience any change in creativity while “highly potent cannabis actually *impairs* divergent thinking” (p. 1123).

Interestingly, one theory is that it may not be the cannabis that make users more creative but that people who are more creative choose to use Cannabis. [LaFrance and Cuttler \(2017\)](#) examined whether cannabis users big 5 personality characteristics contributed to the measurements of creativity by having 412 cannabis users and 309 non-user complete measures of their personality as well as objective and subjective creativity. They found that the “while cannabis users appear to demonstrate enhanced creativity, these effects are an artifact of their heightened levels of openness to experience” (p. 56). A smaller study by [Jones et al. \(2009\)](#) indicated that cannabis users produced a significantly higher number of rare-creative responses than controls.

Psychedelic research was banned for many years but recently there has been increased interest in looking at the potential benefits of microdosing on mental health and creativity: “Recent studies on full-dose psychedelic psychotherapy reveal promising benefits for mental well-being, especially for depression and end-of-life anxiety. While full-dose therapies include perception-distorting properties, microdosing may provide complementary clinical benefits using lower-risk, non-hallucinogenic doses” ([Anderson et al., 2019](#), p. 731). [Anderson et al. \(2019\)](#) completed a quantitative study with 909 participants recruited on Facebook, Twitter, and Reddit. They found that microdosing participants in their study scored significantly higher on the Unusual Uses Task than non-users. [Prochazkova et al. \(2018\)](#) completed a study with the Dutch Psychedelic Society using psychedelic truffles in which participants completed the Picture Concept Test and Alternative Uses Task which both are related to creative problem solving. Participants (55) who took psilocybin showed improvements in divergent thinking and emotional empathy in a study by [Mason et al. \(2019\)](#). Importantly those improvements persisted the next morning in 50 of the 55 participants and seven days later in 22 of the participants.

The possibilities for psychedelic research are improving as some promising results encourage governments to allow more testing of substances that were previously banned. (For review of psychedelic research see *How to Change Your Mind*, 2018).

Prescription Drugs

Prescription drugs including painkillers, sedatives and tranquilizers, and stimulants have been abused for many years. Drugs such as Opioids, Valium, Xanax, Vicodin, OxyContin, and methadone show up frequently in ER emergency situations. In a National Survey more than six million Americans over the age of 12 stated they used prescription drugs for nonmedical uses. None of the drugs mentioned above were positively associated with creativity. However they have been a part of the creative culture, particularly in the music and film industry. Prescription drugs have been implicated in the deaths of a number of eminent creative people including Marilyn Monroe, Jimi Hendrix, Elvis Presley, Heath Ledger, Prince and Michael Jackson among many others.

More investigation is needed to determine the influence of Lithium, often prescribed for bipolar individuals. A metaanalysis of 12 studies including 276 participants taking lithium and 263 similar participants indicated “small but significant” impairment in creativity ([Wingo et al., 2009](#)). Other studies indicated that some individuals with manic depression reported improvement in their creativity, especially in combination with psychotherapy. There is even less research available regarding antidepressants which is surprising given the statistics indicating depression is much more prevalent in many creative individuals than the general population.

One prescription drug may positively influence creativity. [Inzelberg \(2013\)](#) reported that levodopa and dopamine agonists apparently increased artistic talent in patients with Parkinson’s Disease (PD). [Faust-Socher et al. \(2014\)](#) found that 27 patients taking this medication showed “demonstrated enhanced verbal and visual creativity as compared to neurologically healthy controls ... Dopaminergic agents might act through the reduction of latent inhibition, resulting in widening of the associative network and enriched divergent thinking” (p. 935). It is important to note that these drugs have detrimental long term side-effect.

Conclusion

Theories about why the use of drugs and alcohol are more prevalent in creative professions include genetic predisposition, self-medication, opportunity, subculture, the difficulty of the work, the stress of success, as an aid to help their work, widening their consciousness and seeking a spiritual experience.

While conclusions regarding drugs and creativity are very tentative at this point, there are indications that under some circumstances a few drugs may enhance both the expectation of improved creativity as well as creative performance. However much remains to be discovered regarding both the short and long term positive and negative effects. Hopefully the fact that researchers have more freedom to examine the interactions will lead to more definitive answers.

Introduction

A cognitive science approach to understanding creativity will allow for the explication of the creative process on a step-by-step basis. In understanding the cognitive processes underlying creativity, it is helpful to consider broader theoretical frameworks from the area of thinking and reasoning. Dual process approaches to thinking and reasoning have posited the concepts of Type 1 thinking (fast, automatic) and Type 2 thinking (slow, deliberative). Within the last decade there has been increased interest in the role of these two types of thinking, and how they interact, in the process of creative cognition.

Dual Processes in Thinking and Reasoning

Research in the cognitive psychology of reasoning has led to the conclusion that thinking can vary in the extent to which it proceeds slowly, in a deliberative manner, typically constrained by working memory, or more quickly, intuitively or even in an unconscious or cognitively impenetrable manner. Consider the question below:

A bat and a ball cost \$1.10.

The bat costs \$1.00 more than the ball.

How much does the ball cost? ____cents

See Frederick (2005, p. 26).

The answer “10 cents” often occurs to people immediately, perhaps because in similar problems of this nature one simply subtracts one figure from the other. However, evaluation of this response will indicate that this would lead to a total cost of the bat *and* the ball of \$1.20, which contradicts the total cost indicated in the first line of the problem. If this error is caught before a final answer is given, the person can then think through some alternative responses, perhaps using trial-and-error, or working the answer out mathematically:

(Price of bat = x , Price of ball = y)

$x + y = 1.10$ (Equation A: *A bat and a ball cost \$1.10.*)

$x = y + 1$ (Equation B: *The bat costs \$1.00 more than the ball.*)

Replace x with $y + 1$ in equation (A): $(y + 1) + y = 1.10$

Therefore, $2y = 1.10 - 1 = 0.10$

So, y (price of ball) = $0.10/2 = 0.05$

Working the solution out in this manner takes longer than simply subtracting one figure from the other. However, whereas the simple subtraction that works under most circumstances fails here, the step-by-step approach reliably produces a correct answer.

There has been some debate about whether Type 1 and Type 2 thinking can be clearly distinguished; for example, it may be possible that specific thoughts may be described as both Type 1 and Type 2. Although cognition may be thought of as falling along a continuum between clearly Type 1 and clearly Type 2, complex cognition such as creative thinking will likely draw on processes from various points along the continuum. Type 1 and Type 2 thinking have often been referred to as System 1 and System 2, although such phrasing may potentially imply a structural distinction between the two that may not be borne out (at least not in the same way) at a neurophysiological level.

A related question in this area is how Type 1 and Type 2 thinking interact. A default-interventionist model would suggest that Type 1 thinking occurs first, and then may be revised by Type 2, which is more deliberative and therefore slower. In contrast, a parallel-competitive model of Type 1 and Type 2 processing would suggest they are occurring at the same time (Evans, 2007). Although a parallel-competitive model may not apply over a brief timeframe, it is likely that over the course of a longer creative endeavour, Type 1 and Type 2 thinking will occur to differing degrees, and so a parallel model may be applicable over a longer timeframe.

People can be encouraged to use Type 1 or Type 2 thinking to a lesser or greater extent, and then their performance can be compared on creativity tests (see Testing Creativity). Future research may benefit from experimental methods contrasting the two forms of thinking used in the thinking and reasoning literature. These include belief-bias syllogisms, in which researchers vary the logical validity of a syllogism and the believability of the syllogism's premises and/or conclusion. For example, the following syllogism is both logically valid and believable, so should not induce any conflict between Type 1 and 2 thinking:

All dogs are mammals
All mammals are animals
Therefore, all dogs are animals

In contrast, the following is also logically valid, but is lacking in believability, and so should induce a conflict between Type 1 thinking, which would favour believability, and so reject the syllogism as invalid, and Type 2 thinking, which would make it possible to ascertain that the syllogism is valid according to the principles of logic:

All teachers are musicians
All musicians are rich
Therefore, all teachers are rich

Factors such as pressing time limits may make people more likely to rely more heavily on Type 1 thinking. Tasks such as belief-bias syllogisms allow for a direct contrast between logical thinking and less deliberative thinking. This direct contrast can be difficult to capture in open-ended creativity tasks, where even if there is a conflict between Type 1 and Type 2 thinking it may be less clear whether there is a "right" response.

Dual Processes in Creative Cognition: Theory and Research

Folk psychological ideas around creativity, particularly as it relates to genius or ground-breaking innovation, may tend to overestimate the role of Type 1 thinking in creative cognition. Anecdotal evidence abounds about artists who cannot articulate how they came up with a particular idea, or other people involved in creative endeavour who have ideas that come to them "without having to think about it". Some theorists in the area of dual processes have described creativity as a Type 1 aspect of cognition (e.g. Sloman, 1996). However, those studying dual processes in creativity have been increasingly emphasising the role of both types of thinking in creative cognition.

It has been suggested that shifting between Type 1 and Type 2 thinking is important for creative cognition. For example, one idea may rapidly provoke a series of related ideas, but there is generally an iterative process whereby one must shift to Type 2 thinking to compare ideas that "spring" to mind with other ideas in long-term memory. Such an account would be consistent with a default-interventionist model of Type 1 and Type 2 thinking interaction, at least in the short run. At a neurophysiological level, it has been proposed that anterior cingulate cortex activity may act as a neurobiological marker of shifting between generative and evaluative modes of thought (Sowden et al., 2015). This is suggestive of an executive control process in shifting between the two types of thinking; it should be noted that this process in itself may require working memory capacity that is required for Type 2 thinking. Consequently, the delay between a response solely based on Type 1 thinking and a response also based on Type 2 will include the time taken to shift between types of thinking, as well as the time it takes to produce a Type 2 response.

Stage models of creativity (e.g. Wallas, 1926) have proposed a number of different stages in the creative process. Posited stages include problem finding and conceptualisation (where a problem/idea for a creative work is identified, and possible strategies for creative work are identified), incubation (where one stops thinking of the creative task for some time), illumination (where a novel idea forms), verification (where the creative work is checked for quality) and dissemination (where the idea is presented to others). A stage model has been used to elucidate the role of Type 1 and Type 2 thinking at different points in the creative process (e.g. Allen and Thomas, 2011). Allen and Thomas suggested that both Type 1 and Type 2 thinking may underlie creative cognition at all of these stages, with the possible exception of incubation (where an idea is left aside for a period of time, often when someone has reached an impasse), where sufficient Type 2 thinking may remove this stage. Shifting between Type 1 and Type 2 thinking may be employed at any stage of the creative process, and may enhance creative performance.

Illumination/insight has been a stage in the creative process that has been particularly subject to research interest with regard to dual processes in creative thinking. Insight problems have been frequently used in research examining creative thinking and problem solving; these are problems for which people can create different problem representations, and are often likely to create an initial representation which is not conducive to finding a satisfying response. Indeed, many such insight problems are deliberately phrased in such a manner as to encourage the typical person to create a conceptualisation that will frustrate their efforts to solve the problem. In such cases, a person is likely to reach an impasse. For example, the question “Two children are born on the same day to the same parents but they are not twins. How can this be?” is phrased in such a manner as to make the listener believe that the two children must by definition be twins, even though this is explicitly denied within the question. This impasse may lead people to return to the problem conceptualisation stage, where they may find a re-conceptualisation that allows them to solve the problem (in the example, they may think more broadly of the children as being born in a “multiple birth”, which in turn could lead to a solution; that they are two in a set of triplets). The often reported phenomenological “aha!” moment in creative problem-solving is a likely inspiration for the hypothesis that Type 1 thinking is key to this stage of the creative process.

Despite this “common sense” view that the “aha!” insight is due to Type 1 thinking, an interesting study contrasted thinking aloud about insight problems with articulatory suppression (i.e. repeating irrelevant information aloud); the latter would use up working memory processes that could have been devoted to the insight task (Ball and Stevens, 2009). The insight problems were remote associates tests (i.e. people were presented with three words, such as “cottage, cake, Swiss” and asked to find a fourth word, such as “cheese”, that could be combined with any of the other three words to form a compound word/phrase). For difficult insight problems, they found that articulatory suppression reduced performance, suggesting that at least for more challenging tasks, Type 2 thinking is important for insight; likely “kicking in” when Type 1 thinking does not swiftly arrive at an answer as it does for the simpler problems. Case study work on highly creative individuals has suggested that insights for such individuals can be protracted; the creative projects undertaken by such individuals involve great challenge and last a long time (e.g. Gruber and Wallace, 1999; see also Evolving Systems Approach).

Type 2 thinking is perhaps particularly important for verification, where initial drafts/sketches etc. of a creative work are examined for flaws and potential for improvement. For longer creative works, such as screenplays or novels, there may be a great deal of material to sift through for factors such as continuity of plot and consistency of characters’ behaviour. A lot of such work may be outsourced to editors; nonetheless, the cognitive processes involved in creating the finished product can be quite deliberative and step-by-step.

Stage theories have been useful in parsing the role of dual processes in creative thinking, but to better understand the cognitive style of creative people, one may take the approach of focusing on individual differences in Type 1 thinking and Type 2 thinking, and how they relate to creative performance. In an interesting study, individuals who were more prone to engaging in Type 2 processing made more creative connections on a remote associates test; however, they did not generate more ideas, or more original ideas, for an alternate uses task (Barr et al., 2015). These findings suggest that Type 2 thinking may be particularly useful for identifying links between apparently disparate concepts. More broadly, these results are a reminder of the diversity of methods used to assess creative cognition. Barr et al. distinguished between cognitive style and cognitive ability; it should be borne in mind that “failure” to use Type 2 thinking in a task could be a matter of a lack of motivation to use Type 2, rather than weak ability for this type of thinking. Nonetheless, a greater need for cognition in life in general is likely to be associated with greater creative achievement, as such individuals are likely to complete the creative process and see such projects out to the final stages of verification and dissemination of their creative work.

With increasing expertise, thinking processes that may have previously involved a great degree of Type 2 thinking are likely to become more dependent on Type 1 thinking, as they increase in automaticity. Experts with highly developed mental models of their creative field (and consequently a more detailed problem conceptualisation at the early stages of the creative process) may thus identify a novel conceptualisation without having to conduct as much research as a relative novice in the field. This could lead to insight at a more rapid pace, and a scan of the early drafts of an idea can be conducted more swiftly as the creative product is evaluated in more developed “chunks”. The stages of the creative process are therefore likely to differ in how types of thinking are employed with experts.

Applications

A provocative study looked at the generation of ideas for a store to attract more student customers (Dane et al., 2011). The best ideas were implemented by the store itself. It was found that those participants who reported a greater tendency to engage in Type 2 thinking performed better when they were assigned an experimental condition where they were instructed to draw on Type 1 thinking, and those who reported *less* of a tendency to use Type 2 thinking did better when instructed to use Type 2 thinking. This finding is suggestive of an interaction between the two types of thinking in innovative idea generation, and consistent with the hypothesis that switching between types of thinking is conducive to creative cognition. Dane et al. suggested that the use of a non-typical type of thinking may help to “break set”, as well as the possibility that a person encouraged to use a non-typical type of thinking may be more likely to use both Type 1 and Type 2 thinking.

Across various domains of creative endeavour, it is likely that drawing on both Type 1 and Type 2 thinking at various stages of the creative process can lead to better developed ideas. A greater awareness of a person’s tendency to engage in Type 1 or Type 2 thinking will be useful in allowing them to switch to a different type of thinking more frequently. Where there is conflict between the

suggestions of Type 1 and Type 2, it is likely that Type 2 processes will be used in evaluation, which may lead to bias towards the suggestions of Type 2. However, ideas drawn from intuitive, difficult to articulate processes may have great power in artistic domains; where there is an impasse about which output to choose, it is best to seek feedback from an impartial advisor.

Future Directions

Attempts to determine whether default-interventionist or parallel-competitive models of dual processes are more applicable in creative thinking may not be productive, at least with an either/or understanding, as these models may apply to a greater or lesser extent depending upon the timeframe over which creative cognition is studied. It may be more pragmatic to determine when and how individuals may switch between Type 1 and Type 2 thinking in creative work, and whether there are ways for people to recognise (and be taught how to recognise) when this is most of use. There has been some interesting work on training the use of “ideation-evaluation” within a stage theory framework (Basadur et al., 1982); Basadur et al. proposed that ideation is a divergent aspect of creative cognition whereas evaluation is convergent. Nonetheless, there is still a relative paucity of applied research investigating interventions that encourage switching between the two types of thinking in creative performance; there is thus still scope for much future research in this area.

Previous research has examined individual differences in the tendency to engage in Type 1 and/or Type 2 thinking; individual differences in tendency or ability to switch between the two types of thinking may be informative. Such switching may also be associated with creative achievement, although creative achievement may be associated with a number of factors beyond the person’s creative cognition, such as their ability to participate in different domains of creativity and their associated fields. Caution is required to avoid relying too heavily on verbal reports within this area, whether these are based on diaries of exceptionally creative individuals or self-report in a group of research participants. By their nature, Type 1 thinking processes can be more difficult to articulate. In particular, it may be difficult for people to retrospectively introspect on their frequency of switching between Type 1 and Type 2 thinking. It will likely be more fruitful to assess these processes during the creative process, using a think-aloud protocol or experience sampling method, or if possible actively encouraging the person to switch more or less frequently.

Notwithstanding the challenges around self-report, the increased tendency of creative individuals to document their work in online material such as blogs is generating a wealth of material for potential future case studies of highly creative individuals. However, considerable time may elapse between the production of reports detailing the creative process and the recognition of the ultimate creative product as a paradigm shift; one should not overestimate the likely longevity of online material, at least without the maintenance of effort to preserve such material.

Artificial intelligence approaches may help to explicate the role of dual processes in creative cognition. Whereas serial symbolic processing in AI has step-by-step, algorithmic information processing explicitly programmed in, connectionist approaches may capture parallel processing in a manner that is comparable to Type 1 processes that are unavailable to conscious introspection or verbal report. Hybrid AI may help to understand how the interaction between these types of AI can produce novel outputs. Such AI approaches may not only inspire models of human cognition, but also act as a tool for generating creative output.

Brain imaging technologies with high levels of temporal specificity have been of use in evaluating the role of pre-conscious or faster cognitive processes in creative insight. Such findings can shed light on Type 1 processes in creative cognition. With regard to linking brain regions to creative cognition, given the complexity of creative cognition, brain imaging techniques should focus on broader networks of brain activity rather than specific anatomical regions alone (see Neuroscience: fMRI). The default network is one such network, involved in daydreaming, as well as autobiographical memory and episodic thoughts about the future. Another network of interest is the control network, involved in executive function and working memory. The integration of function between the default and control networks may be important in explaining creative cognition (Beaty et al., 2014), and is a likely candidate for explaining how switching between Type 1 and Type 2 thinking is instantiated at a neural level (see Neuroscience: Default Network).

As noted above, Type 1 and Type 2 thinking occur on a continuum, and models of creative thinking within a given creative domain can further articulate underlying aspects of cognition from unconscious to heuristic to algorithmic. A fully developed cognitive science of creativity should account for how aspects of cognition such as categorisation, memory, attention and decision-making feed into creative cognition. To take the example of memory, understanding the dual processes involved in turning an episodic autobiographical memory into a short story would involve understanding how the memory “appearing unbidden” in conscious awareness is gradually tweaked into a fictional story that no longer recognisably resembles the memory of the experience.

Dynamics and the Creativity Process

According to a dictionary definition, *dynamics* can be intended as “A pattern or process of change, growth, or activity.” Adopting a dynamic perspective on the creativity construct is therefore corresponding to the conceptual operation of placing the largest emphasis of the discourse in all those aspects which are subject to change with time, in combination with the variables of space, individuals, environments, and culture. Following the classic 4Ps terminology introduced by Rhodes (1961), this corresponds to giving highest priority to the analysis of the creative *process*, considering a flow of activities and conditions, such that the creative person, product, and press are all seen under a time-dependent point of view: the person’s creative potential and creative achievements in their developmental, operational, and life-time aspects; the product in its position inside an evolution of the culture pertaining to a knowledge and/or material domain, as well as cross-domain; the press as a sociocultural force determining variable success of a process, a person, and/or a product, within a culture or across cultures. The fact that a dynamic perspective shifts the focus of interest onto the process is also in agreement with the ideas expressed by Runco (2019). Conversely, a static perspective on the creativity construct considers achievement and recognition of creativity at a prime, giving priority to the creative product, and reading the person mainly as the author of creative products and actions, the process as leading to creative outcomes, the press as a facilitator or inhibitor of the success of a product at a certain time epoch. Clearly, creative achievement is the goal of a creative activity and its importance cannot be overestimated; at the same time, it is important to clarify the distinction between these two approaches, and in doing so, one discovers the importance of those periods of time in which the creative process is not met with any form of success. From a philosophical point of view, the static versus dynamic duality of perspectives could perhaps be traced back to the classic dichotomy between rationalism and pragmatism (Shalin, 1986), the terms of which are well explained by William James: “For rationalism reality is ready-made and complete from all eternity, while for pragmatism it is still in the making” (James, [1907] 1955:167). In other words, taking on a dynamic perspective on creativity studies can be seen as the adoption of a pragmatist, rather than rationalist, point of view on the subject, placing one’s concern on development more than existence, on trajectories more than equilibrium points, on estimation more than judgment, on processes more than products.

The Dynamic Definition of Creativity

In order to introduce a dynamic perspective on creativity studies from their foundation, it is necessary to adopt a definition of the creativity construct that is in line with the premises of pragmatism. As well known, the debate on the definition of creativity has been and continues to be a long one, being essentially concentrated on the search for the optimal number of criteria to be included in the definition itself, as well as their nature. As we discuss shortly hereafter, the number of criteria is actually not the main concern when we are interested in introducing a dynamic perspective. Given this consideration, the so-called standard definition of creativity (Runco and Jaeger, 2012), specifying two criteria for the existence of creativity, can be taken as a valid starting point for our discussion. This definition posits that *creativity requires both originality and effectiveness*. It is evident that this standard definition requires the presence of an observer and the recognition by this person of some form of originality (subsuming novelty, surprise, and authenticity) and effectiveness (which is domain specific) in what is observed. In doing so, this definition points to the recognition of an instance of creative achievement at a certain time and place, and in this sense, it should be considered to be static, i.e., concerned with a snapshot of creative success. Depending on the level of the achievement under consideration, this recognition could be personal, professional, or even disruptive for an entire domain of knowledge, thus becoming an important part of the cultural

evolution of the human species. However, this definition is not sufficient to cover the entire phenomenology of the creativity construct under a dynamic perspective, for the following two main reasons.

First, when a person, a group of persons, or even a society engages in a creative process, there may be a long period of time during which no outcomes are produced, no problems are solved, no effective ideas are generated, no innovative products emerge, with all trials appearing to fail notwithstanding the efforts and the resources that are poured into the creative endeavor. This means that the creative process in general includes possibly long periods of time in which originality and/or effectiveness (or whatever other criteria one should desire to adopt) are not recognized by anyone: these phases are actually of critical importance under the dynamic perspective, and as such they *must* be included in the definition of creativity.

Second, whenever out of a creative process explicit outcomes should appear, under the pragmatist perspective no single person is entitled to pronounce a definitive judgment on their originality and/or effectiveness: the best one can do is express a subjective assessment, an estimation of the values connected to the appearance of this product, which can always be the subject of a debate. The pragmatist maxim by Peirce applies here: “Consider what effects, which might conceivably have practical bearings, we conceive the object of our conception to have. Then, our conception of those effects is the whole of our conception of the object” (Peirce, 1992-1999, p.132). When an original object appears in front of us for the first time, our conception of this object requires an exercise of imagination of all of its possible effects which might have practical bearing on possible future realities: no one can close such an immensely vast and open-ended exercise, irrespective of one’s level of expertise in any knowledge domain. It is also quite possible that experts’ opinions will diverge, once this freedom is actually taken advantage of. Indeed, the history of the arts, science, and technology has repeatedly shown that the higher the originality of an idea, the stronger the debate induced into the relevant field of experts, typically becoming fractioned into opposing fields of adopters versus opposers of the new paradigm. In essence, requiring absolute recognition of originality and effectiveness in order to allow the existence of creativity appears to be far too stringent a requirement.

For the two above reasons, in order to endorse a dynamic perspective on creativity studies and to cover the entire process including generation and estimation phases in all their possible articulations, it is appropriate to adopt the following dynamic definition of creativity (Corazza, 2016): *creativity requires potential originality and effectiveness*. Interestingly, the only difference between this definition and the standard one is the introduction of the concept of *potential* as a fundamental part of the creativity construct, and it is this single word that transforms the perspective from static to dynamic, creating the needed pragmatist space for development, change, uncertainty, and subjectivity. In the course of a dynamic creative process, the level of potential for originality and effectiveness could be high, moderate, or low depending on myriad variables. Then, at a certain time and in a given cultural space, the potential of an observable outcome could be recognized by someone, giving rise to an instance of *creative achievement*, or it could remain totally unrecognized, leaving the process into a state of what can be defined as *creative inconclusiveness* (a terminology that indicates that the creativity episode should not be considered to be concluded). In fact, creative inconclusiveness and creative achievement can be considered to be the black and white extremes of a scale of gray, and the creative process can be visualized as dynamically fluctuating on this scale, at any time instant being it possible to estimate its state as residing on a specific position on the inconclusiveness/achievement scale. Importantly, creative inconclusiveness can be visualized as the other side of creative achievement in the creativity coin, and as such it is fully part of the dynamic creative process, and indeed a crucial phase. The creativity construct cannot be studied by only looking at the positive events in which creativity is recognized, but it is necessary to add the understanding of the important implications associated to the absence of any recognition, either by oneself or by the outside observers, as experienced when the process visits a state of creative inconclusiveness.

States of Creative Inconclusiveness

States of creative inconclusiveness can indeed be recognized in all models of the creative process. For example, considering the classic four stages model by Wallas (1926), the stages of *preparation* and *incubation*, which can involve long time and large efforts, should certainly be classified as states of creative inconclusiveness, and yet they are certainly very important parts of the process. In fact, longer preparation times, which may include multiple definitions of a problem to be addressed, collection of information from multiple sources, inclusion of inspiration from other disciplines, and so on, can significantly increase the potential to produce ideas that will later be blessed by recognition of both originality and effectiveness. The following stage of incubation, in which very significantly no apparent effort is spent on the creative exercise, allows for neural work below the level of awareness, as beautifully described for example by Henri Poincaré (Corazza and Lubart, 2019). Even after *illumination*, the creative process might return to a state of inconclusiveness if the *verification* stage fails in satisfying the initial objectives. Sometimes, one may want to purposefully prolong this state of creative inconclusiveness to explicitly increase the chances for higher originality: in the terminology of creativity practice, this indication is typically given through the advice: “avoid early closure.” In other words, if a person is immediately satisfied by the first outcomes out of a creative process, his/her chances to achieve significant results are typically reduced, since the more original ideas are remote and require prolonged efforts and resisting any temptation to conclude the process due to failures or even small/partial success. Under this perspective, the ability to extend a state of creative inconclusiveness appears to have very important consequences in increasing one’s potential for originality and effectiveness. A paradigmatic example may be seen in the correspondence between Vincent van Gogh and his brother Theo, in which the painter describes his experience of repetitively scraping off initial figures and producing more and more refined versions of the initial idea. As Vincent himself declared (Brower, 1999, p. 686), this behavior was not caused by impatience (or by any form of psychopathology), but by the willingness and strong determination to improve, learn, and pursue perfection. As a consequence, creativity studies under the dynamic perspective can and

should concentrate efforts on the analysis of the characteristics that creative persons exhibit when experiencing states of creative inconclusiveness, finding a correct place within this theoretical framework for known concepts such as tolerance of ambiguity, persistence, resistance to frustration, and so on.

Estimation of Creative Achievement

As discussed above, in a dynamic creative process creative achievement cannot be established once and for all, but it can only be estimated from the point of view of those observers/estimators who are presented at a certain time with the creative outcome. Depending on the level of sophistication of the product to be estimated, especially in terms of its originality with respect to the state-of-the-art, it may be more or less possible to achieve consensus among a given set of estimators. In other words, creativity measurement techniques and experiments that are based on obtaining consensual assessment of creativity levels by a set of experts are certainly adequate for those tests or conditions under which the level of sophistication and associated originality of the products is low to moderate. On the other hand, the higher the level of refinement of an outcome, and the more disruptive its characteristics with respect to the status quo, the more one should study the level of agreement versus disagreement between the involved estimators, avoiding to force consensus and taking into careful consideration all of the different facets of their assessments, trying to understand where and why they differ, in such a way as to allow this plurality of diversified opinions to finally lead to a thorough understanding of the real value of the creative outcome. In a dynamic creative process, diversity of creativity estimation by different experts is richness, and as such it should be preserved and cultivated.

In addition, adopting a dynamic perspective on the estimation phase of a creative process opens a number of research questions, many of which are yet to be explored in full by the scientific community. The following can be considered to be a nonexhaustive list: a) given that the full engagement of an estimator with a creative product is actually a creative effort in itself (i.e., trying to imagine all possible uses of a new idea in all possible future scenarios), which methodologies could be introduced for studying creative performance as an instance of estimation of the outcomes of a creative process; b) how could this estimator's meta-creativity (creative estimation of other's creative products) be measured; as an example, through the number and diversification of the possible interpretations that an estimator is able to conceive of a creative item in a predetermined time interval; c) what could be the impact of embedded cognition on idea estimation, or in other words, how does the environment (including the relevant emotional climate) influence the performance of an estimator; it is in fact conceivable that assessment of an idea would change by modifying the environment (physical or virtual) in which the estimation phase takes place; d) how could the discrimination ability of original ideas be measured (e.g., through the diversification of the possible consequences derived within a set of expert/nonexpert estimators); e) how could historiometric studies be carried out in the realm of idea estimation, as materialized through the diversification in the estimates of originality and effectiveness of a creative outcome in the short, medium, and long term after its generation; f) how could cultural anthropology be applied to creativity estimation, to characterize the diversification in the estimates of originality and effectiveness of a product as a function of cultural differences of the estimators; g) what could be the effects of social competition on idea estimation (e.g., as measured through the correlation between the estimator's own ability and the assigned creativity scores); h) what could produce social bias effects on estimation, as identified, for example, in dynamic effects of knowledge about other estimators' opinions on a specific estimator's assessment of a product; and i) how could developmental and educational experiences in cultivating creativity in a classroom be characterized; what would change in terms of the overall educational effectiveness depending on the ability of an instructor to act as an estimator of the value of the creative outcomes produced by the students, as opposed to playing the role of a judge who assigns definitive scores.

Creative Potential

As well known, the notion of potential occupies an important place in creativity studies, irrespective of the adoption of either a static or a dynamic perspective. It is therefore necessary to clarify the role of this fundamental concept, once that it is introduced within the definition of creativity itself, as in the dynamic definition introduced above. First of all, considering this word from an etymological point of view, "potential" derives from the Latin adjective "potis," which can be given two different acceptations: capable or possible. Capabilities are first and foremost associated to individual characteristics, leading to the concept of individual creative potential. On the other hand, possibilities can naturally be mapped on characteristics of the state-of-the-art of the overall knowledge of the human species (given our state of cultural evolution, what are the next possible steps for the human kind), such that the potential for originality and effectiveness assumes broader and broader meanings by considering organizational, social, sociocultural, all the way to cosmological realms. Given that creativity studies can usefully follow several classification schemes, such as the already mentioned 4Ps by Rhodes (1961), the 5As classification by Glaveanu (2013) in terms of Actor, Action, Artifact, Audience, and Affordance, as well as the more recent 7Cs classification by Lubart (2017) in terms of Creator, Creating, Creature, Collaboration, Consumption, Context, Curricula, the question would be then: in what form does the concept of potential appear under each of these perspectives? Answering this question leads to a broadening of the analysis far beyond the classic study of an individual creative potential, introducing branches of research dedicated to the potential of a creative process under systemic or embedded perspectives, the potential of an affordance under a material perspective on creativity, the potential of an environment under a sociocultural perspective, and so on. In essence, within the dynamic theoretical framework for creativity the concept of potential is pervasive, and its study and characterization could be considered as a guiding light for researchers in the years to come.

Dynamic Phenomena and Methodologies

While the previous sections were dedicated to defining and setting up a theoretical framework for the study of the dynamic creative process, here we address a few specific topics which can now be seen under the light of this framework; in some cases, these topics could not altogether be conceived unless the dynamic creativity framework were adopted.

Trajectories in Educational Contexts

Beghetto and Karwowski (2019) consider the study of creativity in a classroom, explicitly trying to move away from classic static approaches based on standard tests, and introducing dynamic microlongitudinal designs to describe student–teacher interactions and the evolution of confidence beliefs. Their work is based on four assumptions, here slightly paraphrased using the terminology introduced above: a) Uncertainty acts as a catalyst of creative dynamics; b) Creative thought and action emerge from a dynamic process; c) Determinations about creative achievement are based on generally agreed criteria (e.g., originality and effectiveness); d) Estimation of creativity is dynamic and therefore subject to change across time and contexts. As can be immediately realized, these assumptions confirm that the work by Beghetto and Karwowski (2019) fits perfectly within the theoretical framework described above. Given these assumptions, the problem is how to characterize the dynamic creative process within a classroom environment, and the microlongitudinal approach is the methodology proposed by the authors. Essentially, this approach requires repeating measurements on the phenomena under study with a very high repetition rate (e.g., several times per minute), the results of which can then be analyzed either in a qualitative or in a quantitative way. As an example, trajectories of interaction between a teacher and his/her students can be visualized on a two-axes plane, with time in the abscissa and determination/indetermination of the utterance mapped on the ordinates: the resulting graph gives a unique and immediately understandable picture of what has been happening in the course of a creative session, showing how a conversation (perhaps initiated by the teacher) could start from large indetermination and then converge through a creative process to an agreed idea with a potential for originality and effectiveness. From a quantitative perspective, this microlongitudinal setting lends itself, for example, to a dynamic measure of creative confidence, taking relevant measurements before, during, and after the task. The analytical tools to be adopted are less oriented toward the extraction of inter-individual differences but rather of intraindividual differences, such as multilevel modeling and network modeling (Beghetto and Karwowski, 2019).

The Serial Order Effect

One of the most adopted methods for the measurement of the divergent thinking ability, an important component of an individual's creative potential, is undoubtedly the Alternative Uses Task (AUT), according to which the participants should come up with as many as possible unusual uses of a common object. AUT performance can be measured with several parameters, the most common of which are fluency (i.e., the number of responses produced in a fixed time interval) and response originality (as scored through frequency or by external estimators). This is a typical task in which the time dimension plays a crucial role: the process of generating alternatives changes drastically as time goes on and as responses are produced in series, hence the identification of this dynamic phenomenon as the serial order effect (Wang et al., 2017). Typically, in the first minute fluency is maximum but originality is low, as responses draw upon access to memory or alternatives which lie at a short semantic distance from the typical use of the object. As time goes on, fluency is reduced but the potential for originality of the responses grows dynamically, as the individual is forced to imagine uses that he/she has indeed never seen before. The serial order effect has neural correlates that are still being investigated; for example, Beaty and Silvia (2012) discuss how both default mode and executive control networks are involved in the AUT dynamic process, showing that intelligence comes in to moderate the serial order effect: as intelligence increases, the serial order effect diminishes. The investigation of how cognitive abilities are dynamically involved in the creative process is clearly a very fruitful avenue for continued research.

Dynamic Creativity Measurement Techniques

Carruthers and MacLean (2019) consider the implications of the adoption of the dynamic definition of creativity over the measurement techniques typically adopted in the field of creativity studies, with the aim to propose alternatives or modifications that could be capable to capture different nuances of the dynamic creative process. They consider several points and advocate diversified solutions, including: a) the importance of originality *estimation* (over fluency and frequency) in divergent thinking tasks, such as the AUT described above; b) the possibility (and opportunity) to extend Consensual Assessment Techniques to longitudinal studies, to see how consensus could evolve dynamically through time; and c) the opportunity to address not only creative achievement but also creative *inconclusiveness* instances with different self-reports, including the Creative Achievement Questionnaire (Carson et al., 2005), the Creative Behavior Inventory (Hocevar, 1979), or the Inventory of Creative Activities and Achievements (Diedrich et al., 2018), favoring those questionnaires that allow to describe activities with only a potential for originality and effectiveness but no apparent creative achievement.

Dynamics in the SocioCultural Manifesto for Creativity

Glaveanu et al. (2019) advocate that creativity researchers should endorse sociocultural perspectives in their studies, to complement and integrate the more investigated perspective of individual creators. Among the twelve principles discussed in Glaveanu et al. (2019), one is specifically devoted to the discussion of the dynamic framework, under the heading: "Creativity is dynamic in both its meaning and practice." In fact, the manifesto argues that both the understanding and the practice of creativity vary across space and time, and from this descends a difficulty (if not an impossibility) to operate with a reductionist definition of this phenomenon. Originality and effectiveness could be considered as cross-cultural markers of creative achievement, but even this static definition is the daughter of a historical time and geographical place (i.e., modern Western society). While we acknowledge that there is value in a static definition of creative achievement and its use in scientific investigations, at the same time we should always recognize that estimation of creativity is context-dependent, and we should explore not only what is or is not creative but also *why* we identify something or someone as creative (or not). As discussed before, the authors of the manifesto agree that a dynamic approach to creativity shifts the attention of researchers to the process underlying creative activity and to its potential to produce outcomes that impact possible futures.

The Dynamic Universal Creative Process

A final extension of the consequences of the adoption of a dynamic perspective is in order to conclude this entry. A static approach has the characteristic that, once the judgment on an outcome of a creative process has been given, that instance of the process could effectively be considered as ended. On the other hand, if the dynamic perspective is adopted, and specifically the fact that creativity involves a *potential* for originality and effectiveness, and that this potential evolves through time, it is correct to ask if it is possible to precisely delimit the start and the end of what we could identify as a *dynamic creativity episode*. Upon reflection, it becomes apparent that the dynamic creative process can neither have a clean slate start (we cannot create ex nihilo) nor a unique end, anywhere at anytime. In other words, it is always possible for a creativity episode and/or for its consequences to continue to evolve indefinitely in the future, as a minimum according to the following four mechanisms, as discussed in (Corazza, 2019). First is the mechanism of *continued exploration*, which corresponds to the case when the creative person (or persons) continues to invest resources in an episode irrespective of being in a state of creative inconclusiveness or creative achievement. No prefixed mandatory termination can be envisaged for this exploration phase, as the goals of a worthy creativity episode can be passed on from person to person, or even from generation to generation. Second, even in the presence of creative achievements by a person, the dynamic creative process can and will still continue, typically through the eyes of others: *creativity estimation*, which is an integral part of the process, can continue across time epochs, and ideas that once were not considered to be of any use, could in the future turn out to be of seminal value (or vice versa). The history of science and technology is ripe with instances of this kind, such as, for example, the drawing of a parachute by Leonardo da Vinci, four hundred years before it could actually be realized. Through this extended phase of creativity estimation, every creative episode has the potential to generate long waves of cultural evolution. Third, the outcomes of a creative episode might become the source of a subsequent creative activity. Indeed, the creativity episodes occurring across the cultural evolution of the human species could be shown to be either directly or indirectly *concatenated*: for any achievement of today, we could identify the elements introduced by previous generations that turn out to be the enablers for new progress. Fourth, we should recognize that the potential for originality and effectiveness of the product of a dynamic creative process is not limited by the goals that were initially intended by its creator. In the emerging dynamics, a product might acquire in the future a totally new functionality, and thus be transformed into a completely new creative achievement, which in some cases could be much more significant than the original one. In evolutionary biology, this functional transformation is identified as *exaptation* (Gould and Vrba, 1982), to indicate those new features of an organism that enhance its fitness, but that did not come through Darwinian adaptation.

The main consequence of this discussion is the following: accepting the proposition that the dynamic creative process cannot have an intrinsic predetermined closure, being extended indefinitely in the future through the mechanisms of continued exploration, creativity estimation, concatenation, and exaptation, all creativity episodes can be conceptually concatenated and concur to form an overall process that produces our cultural evolution, an integrated process which we can identify as the Dynamic Universal Creative Process, defined as follows: "The active ensemble of all creativity episodes in the course of cosmic evolution" (Corazza, 2019). This macroscopic view of the creativity phenomenon as a dynamic process appears to be in line with that proposed by Alfred North Whitehead, who in his manuscript entitled "Process and Reality" (1978/1929), discusses a cosmology in which creativity is the ultimate metaphysical principle (p.21): "Creativity is the universal of universals, characterizing ultimate matter of fact. It is the ultimate principle by which the many, which are the universe disjunctively, become the one actual occasion, which is the universe conjunctively. It lies in the nature of things that the many enter into complex unity."

Introduction

Few notions convey a depth of ambiguity equal to “eccentricity.” Its early use was as a scientific description of deviation in the elliptical motion of orbital objects (Merkin, 2014). However, it was co-opted to mean, at least at an inferential, surface level an identity guided by “peculiar” actions that deviate from convention (Gill, 2009). At a deeper level eccentric individuals are characterized as being both mentally ill and joyful; they are both cultural icons and transgressive outsiders; they are both objects of admiration and of pity.

There is, underneath all this contradiction, a deeper, more tangible character that eccentrics are individuals who live at the margins of society and “normal” social order (O’Connell, 2017). Eccentrics are therefore, by virtue of their “otherness,” not representative of norms in collective identity (Kroflic, 2007); they are not, in other words, “centric” to mundane values and banal courses of action in everyday society.

And yet, eccentrics persistently attract attention because of their uniqueness and the dynamic perspective this can lend to interpretations of their work: Great artists, poets, mathematicians, and scientists are known for their quirks and often discussed in terms of their bizarre and creative genius. Similarly people are perennially enticed and titillated by the uncanny, the exotic, and the transgressive, which individuals long to experience, if only from a safe distance (as in Stallybrass and White, 1986). In this way, there seems to be an elementary subject–object relationship to eccentricity as a human experience: Depending on the observer and the narrative of marginality to which they are susceptible, the quality of being eccentric is transformed.

Building from this definition of eccentricity, three deeply interrelated themes can be articulated: That (1) eccentrics are, in themselves, simply marginal individuals whose exploits are to be considered primarily on the basis of that condition, that (2) eccentrics are happy nonconformists who, by various means, choose to accept their outsider status in a positive way, and that (3) eccentrics are unhappy, tortured individuals whose social marginalization is a symptom of a chronic disease of the mind (Weeks and James, 1996). These themes are not mutually exclusive; they are interpretations situated in a particular social and historical context.

In the following sections, each of these themes will be explored with attention afforded to the manner in which the term “eccentric” is utilized by proponents and detractors, as well as the circumstances which may have promoted such an interpretation. The consequences of adopting the theme will be considered, as well, most especially concerning conceptualizations of the creative personality, as elements of nonconformity, strangeness, joyful weirdness, and madness may be indicators of an individual’s tendency toward eccentricity and creativity in equal measure (Weeks & James, 1996), and it seems undeniable that there is some shared relationship.

Eccentricity as Life in the Margins

Before eccentricity connoted either joy or insanity in the popular imagination, it was figuratively associated with a concern for social deviance (Merkin, 2014) and a highly specific, complex fascination with those persons who might constitute a “grotesque” or

[☆] *Change History:* September 2019. Jeremiah Pina updated the text throughout the article.

This article is an update of J. Piña, Eccentricity, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 422–428.

socially unclean station (Stallybrass and White, 1986, pp. 22–24). Thus, it should be no surprise that this use of the term has encompassed many socially marginal and stigmatized categories of individuals, including sexual minorities, racial minorities, and the disabled (O’Connell, 2017).

As Gill (2009) identified, it was this expansion of the concept of social deviance, rife with its implicit references to social station and a fear of “savage” minorities, that would later take root in broader Western culture. Among these were gender-bending aspects of the eccentric French “dandy,” which problematized notions of singularity, vanity, flamboyance, and aspirational fashion (2009, pp. 71–74), and the fraught character of the Parisian Bohemian, whereby authors and artists mediated (and, at times, celebrated) the seedy underworld of the “Paris inconnu” (2009, pp. 175–177). These depictions created a carnivalesque concept of marginal eccentricity perceived through the lens of the exterior tourist, the dilettante, or explorer—within reach of a middle class in pursuit of easy status and pleasure, and just as quickly divested.

There are suggestions, too, that such efforts at labeling underclass marginal individuals as “eccentrics” in this way had, at some psychological level, a secondary purpose: an effort on behalf of the social majority to “tame” unruly outsiders by rendering them familiar and, therefore, harmless. As Kroflic (2007) pointed out, the once-salient archetype of the Court Fool, drawn from medieval European observations of foreigners and the mentally ill, had largely, by the modern era, been relegated to the considerably smaller “roles of the local eccentric and the clown, who are allowed to speak about the unspeakable truths of existence at the price of exclusion from normalized society” (p. 37). Perhaps capturing the ethos of this position more directly, the critic Mark Storey complained that the work of the highly nonconformist novelist and poet Stevie Smith would suffer from her being labeled “eccentric” as, in his estimation, “Eccentrics are not dangerous. [...] Their value fades in their passing” (Blumel, 1998, pg. 112).

O’Connell (2017) argued that the ambivalent attitude toward social marginality and eccentricity—individuals being different enough to merit some concern but safe enough to avoid serious censure or legal penalty—has noteworthy consequences in our modern world. Increasingly, the understanding of disability, discrimination, and the value of diversity are calling to question the concept of “normalcy” as the (de facto) default condition of identity (O’Connell, 2017, pg. 353). This is, in part, due to social and biomedical advancements that have occurred in recent decades, whereby more accurate diagnosis and incremental destigmatization of mental illness have led to unusual, odd, or marginal behavior being classified as relatively minor and benign expressions of disability (2017, pg. 255). As a corollary, eccentricity has become a salient topic in critical postmodernist arguments against the historically binary categorization of “disability” and “normality,” most especially as highly variant—and therefore seemingly strange—self-expression is often bound up in the efforts of social minorities from all walks of life to make meaning from their experiences (2017, pg. 355–356).

This is perhaps no more clearly seen than in creative works that constitute the notion of “outsider art.” Here, the genre classification fundamentally depends on the background and experiential viewpoint of certain artists who are, in this case, “people with no formal artistic training, who are isolated from the dominant culture and the mainstream art world, and who create art that is idiosyncratic or without precedent” (Wojcik, 2008, pg. 179). A common link found among outsider artists is that they most often find themselves drawn to creative action as a means of coping with various forms of adversity, as, for example, Chester Cornett did as a response to his challenges dealing with his children’s disabilities, the consequences to his employment prospects and the stability of his marriage, and his own feelings of isolation and paranoia (Wojcik, 2008, pg. 187). In this way, creativity can be seen as a therapeutic balm to traumatized individuals who might also be suffering from marginality and, for some, mental illness (2008, pg. 194).

What, if anything, is the value of this thematic perspective of the marginal eccentric? Possibly, it is in its ability to convey a sense of the basic, unadorned humanity at the core of eccentricity. We are, all of us, potentially the outsider to some group of people. Marginality is highly contextual, and so “eccentricity” is an identity status that can apply to anyone. And yet, it is seldom willingly adopted by outsiders, being instead more often determined by others. In this way, eccentricity can be seen to indicate a stereotypical social role that has become more common, and therefore more recognizable, in the wake of technological and cultural advancements that put people into contact with a greater diversity of people. But this use of the term, with its history as a euphemism, is not wholly neutral: It conveys a sense of the imbalances of power experienced by marginal groups and the reciprocal relationship of subjugation and fascination that accompany such interactions.

Eccentricity as Happy Nonconformity

It has been historically demonstrated that certain individuals undertake to choose a life of eccentricity, warts and all, as a means of successful self-expression and thereby find themselves happier for the decision. This is a perspective on “eccentricity” as understood, for example, in the writings of Dame Edith Sitwell (1957), who, in her landmark compilation, detailed the lives of several dozen British eccentrics. Nearly everyone of these individuals were eminent—that is to say, famous, noteworthy, and highly respected—personages engaged in high positions in the military, medicine, writing, or aristocratic society. Here, Sitwell might well have been making for herself a host of good company, as she was considered to be a notorious eccentric with similar characteristics to the people in her book (Weeks and James, 1996).

Sitwell’s view of happy nonconformity is one which also has since emerged in the study of eccentricity as a topic of direct systematic review. In their (1996) book, Weeks and James detailed their investigation of the traits of some 789 self-identified eccentrics utilizing qualitative and quantitative methods as varied as informal conversations, structured interviews, and psychometric

inventories. [Weeks and James \(1996\)](#) found a convergent set of 25 characteristics shared by the greatest number of participants in their study, some of which included:

- Enduring nonconformity
- An enduring and distinct feeling of differentness from others
- Creative
- Strongly motivated by exceedingly powerful curiosity and related intellectual exploratory behavior
- Idealism, wanting to make the world a better place and the people in it happier
- Happily obsessed with a number of long-lasting occupations
- Intelligent
- Opinionated and outspoken, convinced that they are right and the rest of the world is out of step with their ideas
- Noncompetitive
- Not necessarily in need of reassurance or reinforcement from the rest of society

Of these, the first five characteristics were considered both the most valuable and the most widely represented, though Weeks' unofficial addendum to the list was that eccentrics are "happier than that rest of us" (1996, pg. 27). Nevertheless, the primary identifying feature of eccentricity was noted to be a tendency toward nonconformity ([Weeks and James, 1996](#), pp. 27–28). Here then, we see evidence of an implicit, but highly significant, reciprocal relationship in this construction of "eccentricity": That there is a condition of nonconformity that essentially depends on the happiness and success that it entails, as well as the joy and positive creative self-expression it promotes, as the basis for understanding the identity. As such, one cannot understand [Weeks and James \(1996\)](#) characterization analytically as being a sum of these qualities and the positive affective states they evoke, but instead must think of eccentricity as a transcendent virtue of the traits in combination.

However, central as it is to this notion of eccentricity, nonconformity in itself poses something of an intractable problem for maintaining a socially neutral framework for the construct, especially as it relates to status. As [Ridgeway \(1981\)](#) posited, the desire for nonconformity bears considerations of social status, perceived competence, and motivation. Thus, it is generally thought to be desirable to enact nonconformity in ways that confer status, and it is undesirable to fail to conform in ways that might impose stigma. As [Sitwell \(1957\)](#) indicated, a corollary of this perspective is that high-status, eminent individuals are seen to be happy nonconformists because implicit and explicit attributions are made to the unique, individualistic (and, therefore, nonconformist) characteristics of an eminent person. But, as [Marcus \(1995\)](#) identified, it is likely that the relationship is more complex and textured, with eminence, and not nonconformity, possibly guiding the narrative—or, as he has stated:

From the perspective of the social judgment and attribution of eccentricity to particular persons, especially of great wealth, power, or celebrity, eccentricity is often associated with the distortion effect or excess associated with the bearing of great wealth or exercising of great power. That is, merely bearing great wealth or exercising great power is quite exotic in the imaginations of most people ([Marcus, 1995](#), pg. 48).

But, at the same time, the value of nonconformity has also been linked with positive personal qualities which comprise universal elements of intelligence and creativity: [Dollinger et al. \(2002\)](#), for example, have cultivated insights of this type by means of a small series of studies that assessed 591 participants in terms of their tendency toward individuality, their willingness to engage in intellectual pursuits, their openness to experience, their need for cognition, and their curiosity. In service of this effort, the authors utilized a mixed-methods design, incorporating diverse indicators of personality, including photo essays, self-report academic disposition surveys, and psychometric scales. Their findings supported "the general proposition that individualistic persons provide evidence of an inquiring intellect much more than their conventional peers," and further contributed to the suggestion that "as a kind of self-applied creativity, individuality seems to begin in ideas about who one might become" ([Dollinger et al., 2002](#), pg. 223).

More broadly, it is a distinct celebration of the individualistic, creative, and successful person which, to some extent, drives the shared comprehension of "stereotypical"—if that word can even apply here—"creative geniuses" and, by consequence, the creativity attributed to their works. [Van Tilburg and Igou \(2014\)](#) compared the perceived eccentricity of an artist and the tendency of everyday individuals to assign creative value to their products. [Van Tilburg and Igou \(2014\)](#), in a variety of settings, identified a "stereotype confirmation" effect by which creativity and eccentricity are related via shared associations in the stereotype. For instance, in one study where participants were randomly selected to learn of Van Gogh's bizarre actions, including severing his ear, they evaluated his art as being more creative than participants who did not receive the stereotype stimulus. Across five such studies, the researchers came to the conclusion that "creative endeavors are clearly not solely determined by the quality of the creative outcomes but also depend crucially on the perceived degree of eccentricity of the artist—a characteristic that is peripheral to the artwork but nonetheless impactful for its evaluation" ([Van Tilburg and Igou, 2014](#), pg. 103).

This raises an important question: If the theme of marginality conveys humanity, what is to be learned from the perspective which treats eccentricity in such a celebratory manner? Perhaps it is that eccentricity, for some, represents their aspirations for success and social regard. In this view, the eccentric person is valued and respected for their contribution to society but also free enough that, should they choose, they might wear clothing made entirely of meat. Clearly, too, there is some common tendency among the notions of eccentricity, nonconformity, and individuality which are associated with the psychological freedom experienced by

artists and writers. That this seems to include qualities of creative individuals as perceived in society is a powerful insight: Are creative works that are carried out by mundane people somehow worse than those carried out by bizarre eccentrics? Is there a quality to eccentricity that enlivens even work lacking in technical execution, making eccentricity its own cause for creativity? Is there a psychological tendency to impose characteristics of eccentricity into the personal narratives of eminent artists even where none exists?

Eccentricity as Mental Illness

There is no denying that “eccentricity” denotes mental illness. [Tantam \(1988\)](#) traced the likely origin of this use of the term in an effort to categorize mental illness in the dawning days of what would eventually become abnormal psychology. Thus, it was from Kraepelin, the founding father of psychiatry, that eccentricity implied something in the nature of “dementia praecox” and from Bleuler, who coined the terms “schizophrenia” and “schizoid,” that eccentricity was first associated with his early conceptualization of “autism.” And, to be clear, these are not attributions that have faded, in any way, over time: A quick review of the Diagnostic and Statistical Manual revision 5 (DSM-V: APA, 2012) reveals, among the modern diagnostic criteria for the “Cluster A Personality Disorders,” inclusive of paranoid, schizoid, and schizotypal personality disorders, the traits “Odd, bizarre, and eccentric.”

As such, one necessary step in justifying eccentricity from the position of happy nonconformity, as above, has often been to distance the term from these clinical usages. And, for their part, [Weeks and James \(1996\)](#) did an admirable job, as they organized their study, of disentangling the two perspectives by means of empirical assessment. That is to say, among a subset of their participants, that [Weeks and James \(1996\)](#) recruited 130 self-identified eccentrics who agreed to take the Present State Examination, an interview procedure by which they would be able to assess certain mental disorders. They reported that only 8% of their participants displayed even mild symptoms of any of the Cluster A personality disorders—higher than the population at large, but by no means an all-inclusive characteristic of eccentrics in their study. Further, the authors distinguished the mental capacities of their participants, most especially those related to the productive generation of mental imagery, from those of individuals with schizophrenia:

One common trait of eccentrics is that they often experience mental images that are more vivid than those of normal people. Some extreme eccentrics have visions, which is a not uncommon symptom of schizophrenia. The important distinction is that the schizophrenic has no control over his visions and the voices he hears; they intrude themselves upon him forcibly and give rise to a terrifying sensation of powerlessness. The eccentric, on the other hand, is likely to find his visions a source of delight, and he has much more control over them. The psychotic state severely disrupts thought processes, leaving the person dysfunctional, whereas the eccentric’s brain usually functions perfectly well – it just does so in peculiar and largely unknown (and unknowable) ways.

Apart from efforts to differentiate what is essentially “good,” or functional, eccentricity from “bad,” nonfunctional or maladaptive, eccentricity, there are attempts to understand the condition of eccentricity itself from the position of how it is understood by individuals with mental disorders. To this end, [Ellerby \(2015\)](#) reflected on his own experiences as an eccentric in light of receiving a diagnosis of schizophrenia at age 22. His perspective was that his “madness,” whatever that might entail in his life, could only be “trivialized” by being labeled an eccentric:

Eccentricity may be a characteristic displayed by some mental patients, but being eccentric itself is a behavior choice. If we look at the mad hatter’s condition [for example] under a modern day perspective, it is clear that he had not much choice in acting the way that he did; he was truly sick. Calling him eccentric diminishes his true issues. That is where trivialization becomes a problem

Ellerby (2018, pg. 466)

Likewise, there have been efforts to determine what, if anything, the status of being labeled an eccentric might contribute to the long-term health of individuals with chronic mental illness. [Tantam’s \(1988\)](#) interviews with 60 psychiatric patients identified a relationship between odd or “eccentric” behavior and lifelong isolation. Tantam found uniform antisocial interpersonal behaviors, including a propensity toward violent crime, as he came to describe his participants unanimously as being “profoundly socially handicapped” (1988, pg. 777). Here, the value of Tantam’s research is not found in the direction of the proposed correlation between identifiers of eccentric isolation and social perturbation—which is entirely expected—but instead in the magnitude of the effect: It is disheartening and sobering to learn that, for instance, the majority of eccentric participants in his study were unable to live alone, and that many of them assaulted members of their own families (1988, pg. 782). Furthermore, these findings frame conditions under which eccentricity might not be seen merely as a trivial condition referent to chronic mental illness.

And what does this understanding of eccentric mental illness say about creativity? It has been proposed that the triune relationship among creativity, eccentricity, and mental illness or “madness” may be one of balanced contrasts. In line with this thinking, [Prentky \(2001\)](#) proposed that creativity might entail the “optimal degree of deviation from normal patterns of information processing,” by which we might conceptualize both eccentricity and mental illness to be more distant deviations from the optimally creative margin. The question here is one of the valid linearity in the underlying continuum: Is there indeed a single, linear system of quantities undergirding a person’s divergence in thought, by which “enough” might be thought to be “creative” and “eccentric” according to positive connotations, but “too much” could reasonably be classified “mentally ill”? [Schlesinger \(2009\)](#) did not appear

to think so. She argued that this type of linear relationship in creative extremes is untenable, being based on poor science which has only confirmed a distorted view of creativity according to a cultural stereotype of the “mad genius.” Further, she put forth the position that an individual’s identification according to the stereotype does not represent an alignment of values, but signifies instead efforts on behalf of creative individuals to psychologically protect themselves by providing a “semblance of consistent identity in a life full of occupational stops and starts.”

In the end, it may be the case that understanding eccentric mental illness, as in the other two thematic interpretations of eccentricity, is based on a social value assigned nonconformist behavior. Here, it is perhaps a feeling of fear that historically contributed most to the notion of eccentric mental illness. Oddness in behavior can sometimes be challenging, intrusive, irritating, and scary. It betrays hints of exotic, or possibly egocentric, thinking that can be taken to mean that an individual does not or cannot engage in social discourse in a eusocial manner. Upon experiencing the notable break of an unspoken norm in an eccentric social interaction, reactive fear might well occur in the wake of an individual’s or social group’s lack of capacity to predict what the eccentric individual is capable of doing. In this way, antisocial eccentricity might be viewed as an essential corollary to the behaviors associated with schizoid personality disorders—these being partially communicated by the extremity of their negative impact on an individual’s orientation to social settings. And while it may, at first, seem completely tangential, the topic of creativity here has a particular bearing: For, if unusual thoughts drive unusual behavior, eccentricity becomes a universal indicator potentially signifying both. It may be only through later analysis and interpretation that these experiences make sense because the original intent is uncertain.

Conclusion

All told, what does the effort of tracing a complex, tripartite conceptualization of eccentricity reveal? What, more directly, is the benefit to be gained from expanding understanding of eccentricity beyond Gill’s (2009) description of behavior that is “strange,” “peculiar,” or “odd”? Perhaps, it is in the effort of thoughtful engagement itself: Problematizing the notion of eccentricity invigorates discourse, accumulating layers of additional significance that allow new vantages on old concepts. Alternatively, the benefit of this sort of effort might be in the ability to better humanize eccentric individuals: Internalizing that marginality interrelates with both happy nonconformity and maladaptive behavior affords the capacity to contextualize eccentric individuals in a larger structure of the many, sometimes contradictory, needs and unspoken desires of society. And, finally, it may be that better apprehending eccentricity is a necessary step in grasping the origins of individualistic creative behavior, for, as this article illustrated, in every condition—among the richest and happiest and poorest in misery—persons who take up the banner of eccentricity express themselves in thoughtful, authentic manners that are, at once, somehow more heartfelt and more significant.

In 1994, paintings more than 30,000 years old were discovered in a cave in south-eastern France. Although it may be an early example of art or visual communication, humans did not live very differently at that time from other non-human animals. They lived off what nature had to offer even if evolution endowed the human species with creative potential. However, this way of life, regulated by the rhythm of nature, changed dramatically over the millennia; the invention of agriculture and livestock in the Neolithic era signals the first major economic consequences of creativity, defined as the ability to make productions that are novel and relevant. Human beings became not only consumers of natural resources but also producers, creating, depending on the abundance of crops and livestock, a tradeable potential surplus. This cognitive prowess may seem insignificant to us today because it consisted largely of recreating what nature knew how to create (although cross-breeding animals and plants was a creative act as well as tool making). The accumulation of knowledge necessary for the production of new resources required observation, imagination and testing of different possibilities that only a creative mind could accomplish; these inventions had such economic and social consequences that historians speak of a Neolithic Revolution. From nomadic hunter-gatherers, in a few millennia, people became sedentary farmers on all five continents (see Barker, 2009; Weisdorf, 2005). However, this agrarian way of life gave way later to an urban and industrial period characterizing a second economic and social paradigm shift: the Industrial Revolution (See, for example, a historical account of the Industrial Revolution: Landes (1969)). It is no longer a question of reproducing what nature produces, but of producing material or immaterial goods that only the human imagination was able to conceive from the accumulation of techno-scientific knowledge. Since then, human life has been subject to an accelerated pace of change, both intentional and unintentional, resulting from people's creative desires, which can be more or less freely expressed according to the culture or laws of the communities to which they belong.

This brief historical overview highlights the growing importance of creativity in the human way of life. In 2010, creativity was cited as one the most important characteristic according to more than 1400 CEOs and global business leaders. But this creative capacity is also solicited among employees, who are increasingly being asked to contribute to the collective creativity of their companies. The objective of this entry is to examine the role of creativity in our modern economies and its power as an agent of change.

An Economy Without Creativity

Imagine a fictitious country populated by individuals with creative abilities but whose culture or law prohibits them from using them. Throughout their lives, individuals are required to respect the order of things in force. At school, teachers teach students the accepted knowledge and punish those who dare to question it or try to discover new ideas. As adults, individuals spend part of their available time producing the set list of goods and services according to imposed technologies inherited from the past. Because private ownership of the means of production is allowed and prices are free, the supply and demand for goods and services adjust to market prices and vary according to consumer preferences. The list of goods and services on the market is therefore fixed, but the quantities produced vary according to consumer demand.

Such a market economy, where creativity is prohibited, is synthesized within Robert Solow's macroeconomic model, which proposed a mechanism for the growth of economic activity based on a given technology inherited from the past and two factors of production, labor and capital (Solow, 1956). Workers can thus use tools and machines (capital) manufactured by these same workers according to manufacturing plans inherited from the past to produce the goods and services listed on the known list. In a formal way, the supply of goods and services sold on the markets is represented by the following aggregate production function:

$$Y_t = Af(K_t, L_t) \quad (1)$$

[☆] *Change History:* August 2019. Todd Lubart updated the text throughout the article.

This article is an update of T. Lubart, I. Getz, *Economic Perspectives on Creativity*, Editor(s): Mark A. Runco, Steven R. Pritzker, *Encyclopedia of Creativity* (Second Edition), Academic Press, 2011, Pages 429–434.

where Y_t , the output (i.e., the Gross Domestic Product of the fictitious country), is the quantity of goods and services produced and sold at market prices in the country in year t , K_t and L_t are, respectively, the quantities of physical capital stock and labor used for the production of output in year t , f is the transformation function of inputs (K and L) into output (Y) and A represents the level of productivity with which the country is able to transform these inputs into the output.

Is economic change possible in this fictitious country? If so, can this change translate into economic growth (i.e., an increase in per capita income over time)? Economic change is possible in such a country but it is limited. Some characteristics are invariant. As indicated in Eq. (1), the level of productivity A and the production processes represented by f are constant in this economy. Output Y , capital K and labor L are homogeneous goods, i.e., that their characteristics cannot change. In contrast, the quantities of Y , K and L can vary upwards as well as downwards. For example, labor L varies according to population growth. The capital K varies according to the number of machines manufactured and the number of machines that have become unusable. Output Y depends on the quantities K and L used in the production processes. Economic change is therefore possible but limited to a single source: the variation in the ratio of quantities of factors of production used in production, known as the capital-labor ratio (K/L).

Is this limited economic change sufficient to generate economic growth? Assuming that marginal returns to capital and labor decrease as their quantities increase, Solow (1956) showed that such an economy could grow in the short term but not in the long term. In the short term, the accumulation of capital stock per worker, i.e. the change in the capital-labor ratio (K/L), allows an initially underdeveloped economy to grow temporarily. Growth ends when the return on capital does not allow investment beyond what is necessary to replace capital that has become unusable over time. In other words, our fictitious country can experience temporary development by providing tools and machines to workers and thus produce more of the same official list of goods and services. This capital therefore allows workers to be more productive. Each time workers receive an additional quantity of tools and machines, they produce more but with an increasingly lower return. Workers' productivity therefore reaches a maximum over time when the production resulting from an additional quantity of capital just covers the cost of that capital. Beyond this maximum, the cost is higher than the gain, which reduces workers' productivity. There is therefore a level of the capital-labor ratio above which growth in income per worker is no longer possible. A decline in population growth or a change in individual preferences may temporarily raise the per capita income growth rate above zero, but in the long run, this growth rate will always eventually return to zero.

In summary, a country, where creativity is prohibited, may experience limited economic change and temporary economic growth but not the long-term growth that has characterized Western countries' growth since the Industrial Revolution.

Innovation: The Engine of Modern Economic Growth

Solow (1957) sought to estimate the share of US economic growth between 1909 and 1949 that could be explained by the change in the labor-capital ratio. Despite the difficulty of measuring capital, his calculations showed that whereas US per capita income had doubled over this period of 40 years, only about 12% of this growth was attributable to capital and labor growth. This result has been repeatedly confirmed by other studies thereafter, for the United States but also for other countries. As for the remaining 88% of growth, economists have called it the "Solow residual", i.e., according to Abramovitz's (1956) famous formula, "a measure of our ignorance"!

Solow's work illustrated how the accumulation of factors of production (capital and labor) is a necessary but not sufficient condition to explain the continued economic growth that Western countries have experienced since the Industrial Revolution.¹ Economists have therefore sought to explain Solow's residual.² The roadmap was ultimately clear. It was sufficient to release all the assumptions of invariance in Solow's model:

1. Productivity is not fixed but progresses over time through the critical evaluation of acquired technological knowledge and the production of new knowledge to improve productivity. This change in technological knowledge raises its level, represented by variable A , which becomes A_t in Eq. (1) because it now varies over time.
2. Production processes are not invariant but change with technological progress and the experience (learning by doing) acquired by producers. The efficiency of these production processes improves over time if they are more economical in terms of production factors. The function f , representing these production processes, therefore becomes f_t in Eq. (1) because it can change over time.
3. The labor force L is not a homogeneous force fixed in time. Workers' productivity changes with knowledge acquired at school and in the workplace. In other words, the labor force can also change qualitatively as a result of the progress of knowledge. The labor force thus becomes a kind of capital, human capital, in which society can invest.

Part of this human capital consists of a set of cognitive, emotional and conative resources relevant to creativity. The level of these resources can develop throughout an individual's life and varies mainly between individuals. A large body of research in psychology investigated the precise nature of the set of resources that support creativity. Two points deserve to be highlighted.

¹According to historical statistics by Maddison (2001), per capita income in Western European and North American countries grew at an average annual rate of between 1.5% and 2% over the period 1820–2000.

²These economists belong to the research field of endogenous growth theory. The main contributions of this theory are due to Lucas (1988), Romer (1990), Aghion and Howitt (1992) and Grossman and Helpman (1993). See Aghion and Howitt (2008) for an overview of this literature.

The first concerns the likely non-linearity between these resources necessary for creativity (Rubenson and Runco, 1992; Sternberg and Lubart, 1995). Whereas a minimum level of resources is required to show creativity, excessive amounts of certain resources (such as evaluative ability) may show diminishing contributions to creative performance. The second is a potential inverted U-shaped relationship between knowledge and formal education (Simonton, 1997). School allows individuals to acquire existing knowledge, thus enabling new generations to avoid reinventing the wheel and making known mistakes. However, as the individual acquires existing knowledge, flexibility of thought may be reduced, and calling the acquired knowledge into question may be seen as devaluing one's hard-earned cognitive assets.

- 4/ Physical capital K is no more homogeneous than labor. Workers are able to improve existing machines and invent new ones. The capital can therefore also change qualitatively.
- 5/ Output Y is not an official list of goods and services. Producers are able to change the quality of existing goods or manufacture new ones. The list of varieties of the supply is therefore variable.

Eq. (1) then becomes

$$Y_t = A_t f_t(\alpha_t K_t, \gamma_t L_t) \quad (2)$$

where year t symbolizes the variation of all components of production over time, α_t is the efficiency of capital K_t and γ_t is the efficiency of labor L_t . Production is now no longer a fixed but a variable list of goods and services

$$Y_t = \sum_i^{N_t} p_{i,t} y_{i,t} \quad (3)$$

where $y_{i,t}$ are the quantities produced of these goods and services whose N_t list varies over time. These goods and services are sold at market prices $p_{i,t}$.

All the changes mentioned above are qualitative changes that can be made to the production of goods and services. These qualitative changes are what economists call innovations made by individuals with creative abilities. In economics, innovation can be defined as "the application of new ideas to the products, processes, or other aspects of the activities of a firm that lead to increased value" (Greenhalgh and Rogers, 2010, p. 4).

Formerly, the value created by innovation at the firm level is equal to

$$V = q - c \quad (4)$$

where V , q and c are, respectively, the nominal monetary net value, the nominal sales revenues and the nominal cost of the innovation. The cost of innovation refers to the production costs of the innovation and, in addition, the expenditures on research and development which made it possible to design the innovation before it was produced. This cost thus includes expenditure on capital, labor and intermediate consumption necessary for the design and production of the innovation. The value created by innovation is included in the firm's total profits. If $V \geq 0$, then the innovation is a success. Otherwise, it is a failure.

At the source of any innovative process, there is a new idea and the new idea is the output of a creative process. Psychological research on creativity provides insight into this creative process. Creative ideas seem to come from a combination/association of remote concepts. The association of remote concepts does not proceed in a random way but is guided by a selection process that depends on the knowledge of individuals as well as their emotions. Lubart and Getz argued that emotional information is a key resource in the preconscious processing of concept combinations and certain emotional abilities are essential for the recognition of these combinations. In firms, the creative process is more and more collective. It is therefore essential for them to activate the cognitive and emotional resources of employees to foster the development of creative ideas at the individual and collective level.

An innovation is therefore a creative idea that has found a market opportunity. If culture or law allows individuals in our fictitious country to use their creative abilities, then human creativity can exert a powerful force for change in the economy.

Can the economic change resulting from human creativity fill the remaining Solow residual and thus explain long-term economic growth? Eq. (4) shows clearly that if $V \geq 0$ then innovation brings a benefit to the firm. Economic change is therefore positive at the microeconomic level, i.e. at the level of the innovative firm. But is it necessarily positive at the macroeconomic level? In a creative economy, new goods and services enter the market alongside and in place of existing goods and services. In other words, innovations create new activities and jobs but also destroy existing activities and jobs. This phenomenon, described by Schumpeter (1942) as 'creative destruction', can take place within the innovative firm itself, when it sells several competing products, and between firms. Among the beneficiaries of innovation are the innovative firm itself and other firms that would use this innovation in their production process (see Creative Destruction). This innovation is then either a new good or service entering the manufacturing process (intermediate consumption), a new capital good (factor of production) or a new manufacturing method (production process). In any case, innovation, through an externality effect, offers a value gain to those firms that use this innovation without having created it. Among the victims of innovation are firms that suffer a loss of value as a result of the competitor's successful innovation. But if this innovation does not allow the innovative firm to cover its research and development costs, then the innovation causes it to suffer a loss. Innovation therefore has a positive macroeconomic effect if the value created in the economy outweighs the value destroyed (see Corporate Creativity).

Is this always the case? In a competitive economy, the answer is yes. Every day, firms compete to sell their goods and services to buyers who are consumers in the business-to-consumer market and firms in the business-to-business market. Because buyers'

Figure 1 A Simplified Growth Model of Creativity.

budgets are limited, firms must do everything possible to ensure that the quality and price of their goods and services convince buyers. While competition regulators ensure that free market entry is respected, competition operates not only between existing firms but also with new firms entering the market. This competition is the market incentive that drives firms to use human creativity to improve their supply of goods and services through more attractive quality at the best price. Competition thus promotes the emergence of creative ideas and the market, i.e. the demand expressed by buyers, selects the most efficient. The innovations sold on the market are necessarily the creative ideas that have overcome all the challenges of the competition. To remain or be more efficient, firms must research and succeed in their innovations. Thus, in competitive markets, firms that succeed in maintaining or increasing their efficiency push out those whose efficiency is declining. For this reason, the macroeconomic effect of innovation is necessarily positive (see Fig. 1 for a model of growth processes resulting from creativity) (see Innovation).

How can this net macroeconomic value creation be measured? A first approach consists of using company accounts as a starting point. But because innovation creates and destroys value, it is difficult to identify the costs and benefits of innovation in firms' accounts and thus to obtain, by aggregating these costs and benefits, an indicator of the macroeconomic effect of innovation. The other approach is based on the measurement of economic growth, i.e. the variation over time of firms' added values. However, as already mentioned, economic growth is the result of economic change resulting from a quantitative change in production factors and qualitative economic change resulting from innovation. However, the decomposition of growth proposed by Solow (1957) made it possible to roughly distinguish the two. The Solow residual can therefore be considered as a measure of the macroeconomic effect of innovation. Given the size of this residual in most empirical studies, it can be concluded without reservation that innovation is the driving force behind long-term economic growth.

However, although positive, the creation of net macroeconomic value has an economic and social cost as new firms emerge and create jobs whereas others disappear with their jobs. In addition, the jobs created often require different qualifications from those of the jobs destroyed, forcing workers to undergo lifelong training to adapt to the requirements of new jobs. This reallocation of jobs from declining to innovative firms benefits mainly new generations and the most skilled workers.

Why Do Firms Innovate?

Economists assume that a firm's objective is to maximize its profit. In a competitive market, profit maximization aims to avoid the risk of the firm's bankruptcy. Audretsch (1991) estimated on US data that only one in two firms was still in business after 6 years and one in three after 10 years. The same author observed that US firms that innovated increased their probability of survival.

As already explained, innovative firms that manage to gain a foothold in competitive markets have *de facto* convinced buyers with new, better or cheaper products. As the buyers' budget is limited, there is not room for everyone. This is why innovative firms drive firms that are less innovative or not sufficiently innovative into bankruptcy.

Competition is therefore a powerful incentive to seek innovation. For this, firms have two possibilities. Either they organize within themselves a research and development department to generate creative ideas that they use for their benefit or that they

sell on the market, which can be called the creative ideas market. Either they buy creative ideas from individuals, universities or other firms in the same creative ideas market. Some firms use both possibilities.

But this has a cost that is not always rewarded. There are many innovations that fail, which also explains the high mortality rate of firms. They must therefore decide between the risk of going bankrupt because they do not innovate and the risk of going bankrupt because their innovations fail. Moreover, even if their innovations are successful, firms face an additional risk: the theft of creative ideas in various forms such as industrial espionage, imitation or counterfeiting. This risk is an existential threat not only to innovative firms but also to the economy as a whole because firms cannot protect themselves against this risk on their own. The creative idea is a “good” that is easy to steal because of its particular characteristics. It is an inappropriable good, i.e. the good is non-rival (several people can consume the same good at the same time) and non-excludable (it is difficult or even impossible to prevent others from consuming the good by varying its price). There is therefore a strong temptation for firms to appropriate the creative ideas of other firms as soon as they are communicated and to sell the resulting innovations to buyers who can benefit from them at immediately competitive prices. Everyone benefits from creative ideas except, sometimes, the firms that produce them.

That is where the problem lies. These creative firms invest money in research and development to generate new ideas. If the market price of the innovations resulting from these ideas is not high enough, then the profit of these firms will not cover the initial investment. If competitors can appropriate creative ideas without having to buy them, why should firms make the effort to spend on research and development to produce them? Arrow (1962) showed that production in a market where the good is inappropriable by its producer was socially non-optimal. This market failure is serious.

On the one hand, it is desirable that access to creative ideas be as broad as possible. Indeed, the creative idea is not the result of an *ex nihilo* process. It is always built on knowledge, experience, existing ideas and informational exchanges between individuals. In turn, the creative idea enriches the stock of existing knowledge that will inspire other creative ideas. This stock of knowledge accumulated over time must therefore be a collective ground from which individuals or teams from firms can draw their inspiration. However, it is desirable that the production of creative ideas be rewarded in one way or another, without which the stock of knowledge cannot progress.

The market alone cannot guarantee both the production of creative ideas to increase the stock of knowledge and the widest possible access to it. The probably imperfect solution that market economies have provided to this market failure is legal rules and regulations: the creation of an intellectual property right for authors of creative ideas and temporary legal protection of innovations (patents and copyrights). Thanks to this legal protection, innovative firms make their new ideas available to the public in exchange for a time-limited payment for the use of these ideas by other firms.

Firms can therefore apply for legal protection of their inventions to a patent office, which must decide on their creativity in order to grant it. The first law on the protection of inventions (*Parte Veneziana*) was promulgated by the Republic of Venice in 1474. This law is the historical testimony of the importance of the economic value taken from that time on by creativity and the difficulty of inventors to appropriate this value. Since that time, as evidenced by statistics from the World Intellectual Property Organization (WIPO), the demand for legal protection of inventions has increased steadily, confirming more than ever the economic value of creativity and the vital need for firms to innovate (see Patents).

Creativity: The Unlimited Frontier of Economic Development in a Finite Environment?

Throughout history, humans have exploited their potential to create resources, material and immaterial goods. This production enabled the demography of the human species to grow rapidly and has profoundly changed people's way of life (Livi-Bacci, 2017). Humanity's tremendous economic development is largely the result of human creativity. If this creativity can be encouraged, then economic development will be enhanced. However, creativity, and resulting productivity and economic growth also impact the balance within human societies and between humans and the planet. It will require additional human creativity to solve challenges facing the world, be they environmental or social, which themselves have resulted from activity at the interface between creativity and economics.

Education and Creativity

Creativity occupies a somewhat paradoxical role within formal K12 and higher educational settings. Although educators have long viewed educational settings as a promising context for the development and expression of student and teacher creativity, schools and classrooms have also been characterized as sites of creative suppression. Moreover, empirical work has demonstrated that the relationship between creativity and academic learning tends to be highly variable across schools, classrooms within the same schools, and even at different points of lessons within the same classroom (Gajda et al., 2017).

One way to understand the variable and, at times, paradoxical role that creativity plays in educational environments is to recognize that schools and classrooms, like all contexts, place constraints on creativity. Consequently, the role creativity plays in any given educational environment will, in large part, be determined by how it is conceptualized in that particular setting.

The opportunities and support for creative expression will, for instance, be very different in a classroom that where educators conceptualize creativity as complementing their academic goals versus a classroom in which creativity is viewed as competing with those aims. Recognizing how different conceptualizations of creativity can have different implications for whether creativity is supported or suppressed can go a long way in helping researchers and educators better understand the role creativity plays in educational contexts.

The purpose of this entry is to provide an overview of various ways creativity has been conceptualized in educational environments, discuss implications for creative expression, and briefly highlight directions for research and practice.

A Continuum of Conceptions

The role creativity plays in educational settings can be thought of as ranging on a continuum from contradictory and ancillary to complementary and primary (see Fig. 1).

One side of the continuum displayed in Fig. 1 portrays conceptualizations that tend to suppress creativity (i.e., viewing it as contradictory or ancillary to the goals of an educational setting) and the other portrays more creativity supportive conceptualizations (i.e., viewing it as complementary and primary to education). Prior to discussing each of the four conceptualizations on the continuum and the implications for creativity, it is important to highlight a few assumptions regarding the continuum.

Figure 1 Continuum of Conceptualizations.

As with any continuum, the areas of the continuum do not represent discreet categories, but rather blend into each other. Moreover, as mentioned there is variability in and across classrooms with respect to the role creativity plays in educational settings. As a result, although a given educational setting may tend to be represented by a more or less supportive conception of creativity, there likely will be some level of variability in the day-to-day and moment-to-moment support of creativity in any given environment. Recognizing that variability still remains within any given environment helps avoid characterizing educational environments in overly simplified ways, prevent missed opportunities to study and realize the creative potential in a particular learning environment, and acknowledge the dynamic and complex nature of educational settings.

Creativity as Contradictory

The first position on the continuum represents a contradictory conception of creativity. A contradictory conception refers to *viewing creativity as being in direct competition with academic goals*. This view places creativity and academics in a zero-sum relationship. Consequently, educators who hold this view may feel that using curricular time to provide opportunities for creative expression likely takes away from more pressing and basic academic goals.

An extreme example of the contradictory perspective is represented in the proclamations of the fictional educator, Thomas Gringrand, in Charles Dickens' *Hard Times*:

Now, what I want is, Facts. Teach these boys and girls nothing but Facts. Facts alone are wanted in life. Plant nothing else, and root out everything else ...
Dickens (2012, p.5)

Although Gringrand is a fictional character, the idea of focusing on basic academic facts is a view that occasionally surfaces in the "back to basics" discourse of educational policymakers and designers of school reform initiatives. In the context of this type of educational policy and discourse, aims such as nurturing student creativity are conceptualized as superfluous.

Research on practicing educator's beliefs suggests that teachers tend not to espouse such an explicitly narrow view of the aims of education. There is, however, evidence that some educators hold a contradictory view, which may be a result of the perceptions they hold and contextual pressures they face. Specifically, prior research demonstrated that some teachers tend to favor conforming behaviors in students (Karwowski, 2017). Moreover, there is evidence that even prospective teachers tend to view creativity as being incompatible with academic learning. Prior research indicates that prospective teachers tend to view cultivating the creative imagination as something that should eventually be replaced with a more serious focus on the memorization of academic subject-matter or something that should be deferred until some later point once students have established a firm academic foundation (Beghetto, 2013).

The contradictory perspective differs from how scholars tend to view the relationship among creativity, academic facts, meaningful memorization, and academic learning. Specifically, educational and creativity scholars have traditionally viewed creativity and learning as compatible and mutually reinforcing experiences. Consequently, scholars often raise concerns when an overly narrow focus is placed on rote learning, memorization, recall, and recognition as they tend to assert that it unnecessarily diminishes opportunities to simultaneously foster creative and academic potential. David Berliner (2011), for instance, asserted that such restrictive educational policies and externally mandated testing practices have dire consequences both for creativity and "what it means to be smart in school" (p. 79).

Implications for Creativity

Educational systems which operate under the assumption that creativity and academic learning represent contradictory aims, likely will suppress creative expression and the development of creative productivity. Indeed, if creativity is viewed as taking away from educator's primary responsibility, then it makes sense that, in practice, educators would disapprove of anything that contradicts their primary professional aim. One consequence of this is that even unexpected and potentially creative ideas shared during classroom discussions likely will be deflected (e.g., "We'll talk about this later") to avoid the risk of being derailed from their previously planned academic lesson.

Creative experiences can still operate within the context of educational environments that conceptualize creativity as contradictory. Creativity researchers have long recognized that subjective forms of creativity occur anytime someone has a new and personally meaningful insights, interpretations, or experiences. The problem, of course, is that students need to have opportunities to receive feedback on their own unique conceptions. This is important both for learning and creativity.

With respect to learning, students need to be able to test-out their ideas and receive corrective feedback on any confused, muddled, or inaccurate academic conceptions. As for creativity, students also need opportunities and feedback to help them communicate unique and meaningful conceptions so that those ideas can make a contribution to the learning and perspectives of others. If creativity is conceptualized as a contradictory educational aim then it likely will curtail the encouragement and feedback necessary for creative expression and limit opportunities for students to develop their creative productivity.

Creativity as Ancillary

Moving along the continuum of conceptions, the next way that creativity can be conceptualized in educational settings is to view it as a potentially beneficial but ancillary goal. An ancillary conception therefore refers to *viewing creativity as a valued, but minor aim of education*. Much like conceptualizing creativity as a contradictory goal of education, viewing creativity as an ancillary, albeit valued aim of education likely will result in creativity being differed or dismissed. This is why an ancillary aim falls on the tending toward suppressing end of the continuum (Fig. 1).

Prior research suggests that an ancillary conception of creativity may be the most widely held view amongst educators. Consider, for instance, the results of a systematic review of 18 studies on teachers' perceptions of creativity published from 1999–2015 (Mullet et al., 2016). The authors of the review reported that teachers tend to value creativity but typically believe it is limited to the arts and feel unprepared to foster it in their classrooms. Such beliefs reveal an ancillary perspective. Specifically, when creativity is viewed as valued, but separate from what teachers have been prepared and are expected to teach, then it likely will receive little if any attention.

This ancillary view was also prevalent in the findings of another systematic review of 53 studies published from 2010 to 2015 on K12 teachers' beliefs about creativity (Bereczki and Kárpáti, 2018). The authors reported that teachers tend to hold a generally positive view about creativity (e.g., "generally value creativity", "believe that it can be nurtured in every student"), but also tend to believe that they are not capable of fostering creativity due to various barriers that characterize their professional practice (e.g., "lack of time and training," "overloaded curriculum"). The consequence, as the authors of the review explained is "even if teachers hold positive or adequate beliefs about creativity, these rarely translate into creativity-fostering practices" (Bereczki and Karpáti, 2018, p. 50).

Implications for Creativity

When creativity is a valued yet an ancillary aim, teachers may feel as though it is not their direct or most pressing responsibility. Consequently, opportunities for creative expression tend to be suppressed because teachers feel the pressure (self-imposed or otherwise) to focus on more pressing academic aims.

As mentioned, one reason this can happen is because teachers feel overloaded by their primary academic curriculum. Indeed, teachers who would otherwise "like to help students develop creativity" tend to feel "overwhelmed with other more pressing responsibilities" (Aljughaiman and Mowrer-Reynolds, 2005, p. 30)

Another reason this can happen is if teachers do not feel they have had adequate preparation or opportunities to support creative expression in the context of their academic subject matter teaching. Indeed, Chan and Yuen (2014) explained based on their study of teachers in gifted and general education that supporting creativity in the classroom may come down more to environmental supports, opportunities, and resources to implement creativity supportive practices rather than substantial differences in creative personality or valuing creativity.

Viewing creativity as an ancillary goal of education is not limited to practicing teachers. Prior research on prospective teachers also indicated that they generally value creativity, but tend to view it as being more aligned with the arts and have concerns that spending time exploring creative ideas during the teaching of academic subjects may take them "off track" from their primary curricular responsibilities (Beghetto, 2013). It therefore may be the case that future educators enter into the profession already holding ancillary conception of creativity, which carries over and continues into their professional practice.

Consequently, translating a value for creativity into opportunities to foster students' creative productivity in the curriculum, may come down to educators learning how creativity can complement their academic goals.

Creativity as Complementary

The next point on the continuum of conceptions is a complementary perspective. This perspective *refers to viewing the development of creative productivity as being compatible with academic learning and academic learning as being compatible with fostering creative expression*. A complementary perspective positions creativity and academic learning as having the potential to be mutually reinforcing. It is a both/and perspective, which recognizes that although there are differences between creativity and academic learning there is a positive relationship between the two.

Viewing creativity as compatible with academic learning is a view that has long been held in the creativity studies literature. J.P. Guilford (1950) explained that "a comprehensive learning theory must take into account creative activity" because "a creative act is as an instance of learning" (p. 446). Learning theorists, including Jean Piaget and Lev Vygotsky also recognized that the creative imagination plays a central role in the development of knowledge. Recent theoretical perspectives have also characterize creativity and learning as compatible (see Beghetto, 2016 for an overview).

One reason scholars conceptualize creativity as being complementary to educational goals is because it represents a blend between *originality* (i.e., uniqueness, novelty or effectiveness) and *meaningfulness* (i.e., usefulness, effectiveness or meeting task constraints). In the context of an educational setting, academic subject matter can serve as the task constraints and originality represents different ways for teachers and students to meet those constraints.

Creativity researchers have also examined the empirical link between creativity and academic achievement. A meta-analysis (Gajda et al., 2016) examined 120 studies and 782 effects from research conducted from 1962–2015 and found a positive, albeit

modest association ($r = 0.22$) between measures of creativity and academic achievement. This somewhat modest, yet positive relationship is, in part, due to the variability in the types of measures used and variability of the relationships found in studies included in the metanalysis. Indeed, previous research found positive, negative, and null relationships between creativity and academic learning.

Although there seems to be a generally positive association between measures of creativity and academic learning, a key take-away from the complementary perspective would be although creativity can be compatible with academic learning, there likely is a great deal of variability in how this plays out in educational settings. A recent, mixed-methods study (Gajda et al., 2017), for example, examined the variability of creativity supportive behaviors in ten classrooms classified as having a positive (average $r = 0.52$), negative (average $r = -0.23$), and null (average $r = 0.02$) relationship between creativity and academic learning. The findings from this study suggest that classrooms classified as having a positive creativity-academic achievement relationship tended to be characterized as having teachers who demonstrated caring behaviors, emotional support, more extended opportunities to explore and develop student ideas creativity supportive behaviors. Importantly, however, student self-expression and ideation were found across all classroom types. Moreover, redirecting and dismissal of students' ideas also occurred in all classroom types and there was also evidence that creative teaching and learning behaviors may be difficult to sustain over the duration of the entire lesson.

Taken together these results indicate that creativity can be compatible with educational aims across various classroom types, but that there is variability in when, how, and why creativity plays a compatible role in particular classrooms at a particular point in time.

Implications for Creativity

A complementary perspective therefore recognizes that opportunities for encouraging and exploring creative ideation in the context of academic learning is possible, although not always feasible or necessary during every moment of academic learning. In this way, a complementary view of creativity acknowledges that there is a time and place for creative expression. It is not always beneficial or necessary for students to come up with their own unique way of meeting academic expectations or meeting academic criteria. Indeed, learning pre-existing ways of thinking and acting can not only be beneficial for learning but also for creativity.

In this way, highly planned learning environments, which require students to fulfill predetermined expectations or criteria do not necessarily stifle creativity. In fact, as long as educators blend pre-determined features with to-be-determined aspects, then they will actually be planning for creativity by including opportunities for students to meet pre-established educational goals and criteria in different ways.

A complementary perspective thereby recognizes that educators need not always try to teach creatively or require creative expression on the part of their students, but rather provide young people with frequent opportunities to develop, test-out, and contribute their unique insights and perspectives to what they and their peers are learning.

Creativity as Primary

The final conception on the continuum involves viewing creativity as a primary educational goal. Much like a contradictory conception, the creativity as primary perspective represents a somewhat extreme end of the conceptual continuum. In some cases, viewing creativity as a primary educational aim has historically had a basis in theological beliefs or viewing creativity as central to what it means to be human. Such views have most frequently been evident in the design of early childhood environments.

Fredrich Froebel (1782–1852), the German educator and progenitor of the concept of the kindergarten, represents one of the earliest examples of an educator conceptualizing creativity as a primary aim in the design of educational practices. Froebel's ideas, which had theological overtones, outlined a pedagogical approach aimed at fostering children's creative activity. Froebel based his educational views on his belief that children were inherently creative beings and thereby required an education that provided opportunities for students to engage in creative activity, effort, and development (Hill, 1908).

Other examples of educational environments that viewed creativity as playing a primary, albeit more integrated role include the American Pragmatist John Dewey's Laboratory School at the University of Chicago, which had an aim to "respond to the child's need of action, of expression, of desire to do something, to be constructive and creative, instead of simply passive and conforming" (Dewey, 1990, p. 80). The Reggio Emilia approach to education is another example. Developed after World War II by the educational psychologist, Loris Malaguzzi, in collaboration with educators, parents, and children from Reggio Emilia, Italy. This approach, much like other child-centered approaches (e.g., Montessori and Waldorf), views educational settings as places where "children and adults may realize their full potential as intelligent, creative, whole persons" (Edwards and Gandini, 2018, p. 368).

In addition to early childhood environments, arguments in favor of conceptualizing creativity as a primary educational aim tend to be offered as a corrective to what is perceived as educational settings placing too narrow of an emphasis on memorization and recall. Arguments in favor of viewing creativity as a primary educational goal sometimes position it as being *the* most important goal, which represents the most extreme version of this conception.

The American creativity researcher, Frank Barron, for instance, observed that during the late 20th century in the United States a "growing core" of educators and educational programs endeavored to place "creativity as the most important goal of education" (Barron, 1969, p. 7). Similar views have been asserted in other countries and occasionally resurface across the decades. The British

philosopher, Mary Warnock, argued that educators have a duty “above all else” to develop the child’s creative imagination (Warnock, 1978).

In other cases, arguments in favor of creativity as a primary goal describe it as a distinct but equally important aim as academic learning. The author and speaker Sir Ken Robinson, for example, asserted in his incredibly popular 2006 Ted Talk (*Do schools kill creativity?*), “creativity now is as important as literacy, and we should treat it with the same status.” Gifted education programs have also conceptualized creativity and academic learning as important but distinct curricular streams.

In still other cases, scholars and educators who view creativity as a primary aim also recognized that it overlaps with academic learning and thereby hold views that start to blend with a complementary conception. As mentioned, the Soviet educational psychologist, Lev Vygotsky viewed creativity and academic subject matter as complementary. Vygotsky, however, also asserted that if preparing young people for the future is the main educational goal, then fostering the creative imagination “should be one of the main forces enlisted for the attainment of this goal” (Vygotsky, 2004/1967, p. 88).

Implications for Creativity

Viewing creativity as *the* or *one of the* most important educational goals, can result in multiple opportunities for creative expression. Such educational environments however tend to be an alternative to the prototypical K12 or college educational environment (e.g., early childhood settings, creativity-focused gifted education programs, specialized schools, or after school programs). There are also emerging settings that offer a creative third space for students and educators.

A creative third space provides students with opportunities to engage in creative projects and endeavors in a space between their typical academic program and their surrounding community. *IowaBig* is an example of a creative third space, which provides opportunities for students to take creative action on real-world problems. Iowa BIG is a public high school program, with no admissions requirements, which partners with school districts in Iowa and provides students and families with a “different learning experience” (lowabig.org). Specifically, students attend Iowa Big for 50%–90% of their school day to design a creative, interdisciplinary project that requires students to work with outside partners to work on addressing problems and community needs generated by students and local businesses, non-profits, and government agencies (lowabig.org). Conceptualizing creativity as a primary aim of education can result in experiences tending toward supporting creativity, but such a conception can, somewhat ironically, also result in the marginalization of creativity (at least in prototypical K12 and college settings). Indeed, given that most K12 and higher education systems have already firmly established academics as a primary aim, attempting to replace or compete with academic learning for curricular space likely will result in creativity being displaced or outsourced. Consequently, much like a contradictory or ancillary perspective, educational programs that have a primary aim of encouraging creative expression and fostering creative productivity tend to relegate it to specialized and extracurricular educational programs.

Conclusion

The purpose of this entry was to highlight how different conceptions of creativity can have implications for whether it is supported or suppressed in educational environments. One key insight for both researchers and educators is to avoid the temptation of characterizing educational environments as monolithic. Educational environments do not necessarily suppress creativity. Creativity still occurs even in environments that view it as contradictory to the aims of education and creative expression is also sometimes suppressed in environments that value it and actively attempt to encourage it.

Creativity researchers interested in understanding creativity in educational environments therefore need to take the time to understand the unique features and aims of the settings they are studying. The use of blended methodologies that employ more dynamic and micro-longitudinal designs can help reveal the variability of creative expression both within and across educational contexts.

Moreover, researchers who take the time to work more closely with practicing educators likely will develop a better understanding of the unique constraints teachers face as well as what things teachers are doing to support student creativity. Teachers (both prospective and in-service) can also learn from researchers how creativity has been conceptualized in the field of creativity studies, how it might complement their academic aims and responsibilities, and how to strike a better balance of knowing when, how, and why to support creative expression in the context of their other academic aims.

Introduction

One of the most urgent problems in the scientific study of creativity is precisely how to define the phenomenon. By what criterion does a researcher identify one subject as creative? The published literature is replete with rather diverse operational definitions. Most often, however, individuals are said to display creativity when they score sufficiently high on a so-called creativity test. Yet clearly, such identification only begs the question: How do we know that the psychometric instrument actually measures creativity? Obviously the test must undergo some type of validation. For instance, the test might be validated by determining if those who score high on the measure can generate products or ideas that are judged creative by others. But this merely sweeps the problem under yet another rug. Who shall we rely on to perform these judgments? [See Testing/Measurement/Assessment.]

One reasonable resolution to this measurement quandary is simply to say that individuals who have received broad acclaim for their creative contributions can be safely deemed creative. Such a definition seems sound on *prima facie* grounds. In the parlance of psychometrics, an eminence measure of creativity has “face validity.” Note that creative eminence also solves a host of other methodological niceties as well. For example, another difficulty in the investigation of creativity is how to define different types or levels of the phenomenon. How does the researcher distinguish artistic from scientific creativity? How does the investigator gauge the magnitude of creativity? From the standpoint of the eminence criterion, the response to both questions is direct. Individuals who attained distinction for contributions to the arts are artistic creators, whereas those who earned applause for contributions to the sciences are scientific creators. Therefore, Picasso exemplifies artistic creativity, whereas Einstein exemplifies scientific creativity. Similarly, the higher the level of fame achieved, the greater the presumed level of creativity displayed. By this judgment, accordingly, Johann Sebastian Bach is deemed more creative than, say, Georg Gebel the Elder, his exact contemporary and compatriot.

As the foregoing discussion suggests, the eminence criterion of creativity may be employed two distinct ways:

1. In the simplest usage, eminence is adopted as a sampling criterion. Individuals who exhibit sufficient excellence in a creative domain are selected for inclusion in the researcher’s sample. For instance, when Ann Roe (1953) wished to understand the basis for scientific creativity, she sampled a group of 64 eminent scientists based on expert appraisals. Sometimes the eminence criterion is also used to single out subjects for the control group. A good example is the approach taken by researchers at the Institute for Personality Assessment and Research at the University of California at Berkeley (Feist, 2014). Wanting to understand the basis for creativity in architecture, the investigators recruited the participation of some rather renowned members of that profession. But the researchers also obtained the participation of far less successful colleagues who could provide the basis for comparison. [See Consensual Assessment.]
2. The other role of eminence is as a continuous variable used to measure individual differences in creativity. Just as the amount of creativity may vary from person to person, so may the amount of eminence exhibit considerable cross-sectional variation. To the extent that the fame of creators is founded on the magnitude of creative achievement, the degree of distinction should be directly related to underlying creativity. Such an eminence indicator of creativity is employed three major ways in the published literature. First, the eminence measure may be studied alone. The researcher may focus on the degree of variation, the distribution, the stability across time or cultures, and so forth. Second, the eminence measure may be adopted as a dependent variable in a prediction equation. In such cases the goal is to identify the factors that predict historic creativity. This constitutes the most common use of this type of creativity measure. Third, but less frequently, eminence may be used as an independent variable, especially as a moderator variable in a regression equation testing for interaction effects. For example, some inquires look at

whether the curves defining the relationship between age and creative productivity varied according to how illustrious were the creators (Simonton, 1997). Here eminence “moderates” the relation between age and output. The interest then is not in predicting eminence but in determining whether the same career trajectories held for all individuals regardless of the magnitude of accomplishment. [See *Genius and Greatness*.]

Measurement

What are the ways that researchers go about assessing the eminence of creative personalities? What are the psychometric properties of the resultant eminence assessments? These are the questions answered next.

Assessment Techniques

Once the investigator decides to use eminence in a particular study, the first issue that must be addressed is how to best assess the eminence of the individuals under investigation. Sometimes a purely informal procedure suffices. For instance, most psychobiographical studies of creative individuals select a particular case for study precisely because that person is obviously famous (and at the same time interesting in some other way; Schultz, 2014). Thus, when Sigmund Freud (1910) did his analysis of Leonardo da Vinci, he felt no need to justify the choice of subject. The artist’s eminence would be obvious to all. Similarly, when Howard Gardner (1993) selected the seven subjects for his book *Creating Minds*, he simply picked a 20th-century luminary who represented each one of the seven intelligences according to his theory of multiple intelligence. The resulting sample consisted of Albert Einstein, T. S. Eliot, Pablo Picasso, Igor Stravinsky, Martha Graham, Sigmund Freud, and Mahatma Gandhi. Even though someone else might pick a different set of representatives, the distinction of these seven figures is beyond doubt.

One difficulty with such informal sampling methods is that they permit the potential introduction of bias. Because there is so much latitude for subjectivity, it can happen that the eminent are unconsciously selected to be consistent with some perspective or hypothesis. An interesting illustration is the sample that Abraham Maslow (1970) collected to study self-actualizing personalities. Because, as a humanistic psychologist, Maslow believed that creativity was associated with superior mental health, it cannot have been mere accident that there are no cases of truly “mad geniuses” among the creators in his sample. Sometimes the avoidance of the psychopathological made him sample the less famous rather than the more famous. Why else would Maslow choose Camille Pissaro rather than van Gogh or Franz Joseph Haydn rather than Beethoven? [See *Mad Genius Controversy*; *Self-actualization*.]

To avoid the potential introduction of bias, many investigators adopt more systematic and objective strategies for sampling eminent creators. Sometimes the researcher will study those individuals who have attained sufficient acclaim that they have biographies written about them or at least articles under their name in major reference works, such as encyclopedias or biographical dictionaries. Other times the investigator will rely on peer nominations. Experts in a particular domain will be asked to nominate those contemporaries who have made the most creative contributions. Still other researchers will adopt the criterion of the creator having received a major honor, such as the Nobel or Pulitzer.

So far the focus has been on the application of the eminence criterion as part of a sampling procedure. Yet as pointed out earlier, eminence often figures prominently as an individual-difference variable in its own right. Even among the notables of a particular creative domain, the variation in reputation can be quite substantial. The question then becomes how to best capture this dispersion in terms of reliable scores on some eminence measure. One of the oldest and most common solutions is to use standard reference sources to define some type of space measure. For instance, the investigator might count the number of pages or lines devoted to each creator in a biographical dictionary, encyclopedia, or history. Alternatively, the researcher might count the number of books or articles written about each individual in the sample. Such archival indices of eminence have the advantage of being highly reliable and objective.

However, some investigators prefer eminence assessments that allow more room for subjective considerations. A good example is the Creative Achievement Scale devised by Arnold Ludwig (1995). This instrument requires assessments of an individual’s contributions in terms of originality, universality, versatility, influence, transcendence, virtuosity, and so on. These assessments are based on biographical and historical information available about each eminent creator. Another approach is simply to ask experts to rate eminent creators on the global level of creativity realized. Sometimes such global assessments are carried out in the form of rankings.

In any case, these subjective measures have certain advantages over the objective measures mentioned in the previous paragraph. For one thing, the subjective indicators can help the researcher understand better what exactly is being assessed, especially when the components of creative eminence are made explicit in the design of the measurement scale, as is the case in Ludwig’s instrument. In addition, the objective measures sometimes have biases that are not necessarily present in the subjective measures. For instance, archival assessments of eminence based on space measures often favor some forms of creativity at the expense of other forms. It is much easier to describe in words the contributions of writers and philosophers than it is to give a verbal account of the contributions of painters and composers. As a consequence, encyclopedias tend to devote more space to eminent individuals whose creativity took a verbal form than to those whose creativity required nonverbal means of expression. Fortunately, statistical procedures

do exist that permit the introduction of the appropriate corrections, but these procedures necessarily make the data analysis more complicated.

Psychometric Features

It should be pointed out that eminence measures have been shown to have highly desirable properties from a psychometric perspective. One striking example concerns reliability, which gauges the amount of measurement error. It turns out that indicators of individual differences in creative eminence display quite impressive reliability coefficients, which signify that the amount of measurement error is relatively small. In fact, eminence measures are just as reliable as other, more commonplace measures in psychology, such as scores on intelligence tests. Second, alternative techniques for assessing individual differences in eminence yield quite comparable results. Not only do the diverse kinds of objective measures correlate highly with each other (and the various types of subjective measures intercorrelated highly as well), but in addition the objective and subjective assessments are in substantial agreement as well. Hence, a consensus exists on the relative eminence of creative individuals. Finally, this strong consensus on differential eminence is highly stable over time. Researchers have examined eminence ratings separated by a century or more and still obtain respectable correlations. Indeed, there appears no pronounced tendency for the agreement to decline as the temporal separation between two measures increases. This transhistorical constancy of eminence suggests that differential fame is tapping into some stable individual differences in creative accomplishment. If Mozart is consistently rated as more famous than one of his contemporaries, such as Daniel Gottlob Türk, this contrast no doubt reflects to a very large extent their comparative creativity.

Admittedly, the correspondence between eminence and creativity is by no means perfect. Exceptions to the general rule do exist. Sometimes creators die before they receive the recognition they deserve (e.g., Gregor Mendel), whereas other times creators received far more contemporary fame than they will be granted by subsequent generations (e.g., Trofim Lysenko). Yet these occasions are too few and far between to seriously undermine the reliability and stability of eminence indicators.

It must also be confessed that it is the fairly irreversible fate of every luminary that his or her fame will decline with time. After all, as more and more creative products are added to the cultural store, the competition becomes ever more fierce. Each year there are ever more paintings to hang on gallery walls, compositions to perform in the concert halls, plays to be produced, books to be reprinted, and so forth. Accordingly, even the most illustrious creators are fated to see their market share gradually diminish. Yet that decline by itself does not attenuate the significance of eminence as a gauge of exceptional creativity. So long as the relative positions of eminent creators remain constant over time, the stability of eminence will persist. Hence, in the theater Shakespeare may have had to yield some ground to Shaw and other more recent playwrights, but so did Marlowe, Jonson, and other Elizabethan contemporaries. Despite the increased competition, Shakespeare's differential standing survives unscathed.

Conclusion

The ultimate justification for using eminence as an index of creativity is that it has yielded substantial insight into how creative geniuses differ from their less successful competitors for historic distinction. Highly eminent creators differ from their less distinguished colleagues on a host of cognitive, personality, developmental, and sociocultural variables. To offer a specific instance, the "mad-genius" hypothesis is supported by historiometric research indicating that creative eminence is associated with degree of psychopathology, even if the precise nature of the relation depends on the domain of creative achievement (Simonton, 2014). Thus, eminence is not bestowed in an arbitrary fashion, nor does it lack any correspondence with what is going on in the individual creator's mind.

Definitions of Emotion and Affect

Concept of Creativity

A useful distinction in the conceptualization of creativity is that of the creative product as opposed to the creative process. The creative product is the output of the individual. The output is then judged according to criteria in a particular field as to its creativity. There is a consensus in the field that for a product to be judged as creative, it must be a) original, unique, novel and b) useful—that is, adaptive and aesthetically pleasing according to the standards of the particular discipline.

Given these two criteria for a product to be judged as creative, the question is often asked, “Can children be truly creative?” Although children can generate new and useful ideas and products, the products are usually not at a level of sophistication necessary to truly contribute to an area. However, if one considers whether or not a product is new and good for that age group, then children can be considered to be generators of creative products. Even though a discovery or idea may have already occurred in a field, if it is new to the individual, then it is a creative act. Ruth Richards (1993) has called this kind of creativity “everyday creativity.” Therefore, children and many adults demonstrate creative acts on a daily basis, even though the creative products are not making major contributions to a discipline like art or engineering. This is an important point because it implies that we can study creativity in children and in normal adult populations.

The creative act, which generates a creative product, can involve a number of underlying processes. A major question in studying creativity is “What are the processes that are part of the creative act?” What cognitive, affective, and personality processes are involved in the creative process and increase the likelihood that an individual will generate a creative product?

Concept of Emotion/Affect

It is important to define the terms **emotion** and **affect**. Affect has been described as a broader concept, with emotion and mood as a subset of affect. Emotion is defined as a state of aroused feeling or agitation. Affect has also been viewed as a broad set of events that includes emotions and drives, and involves feeling states that are pervasive. Emotions have been described as interrupting events that are more specific in terms of stimuli and behavioral responses that are broader feeling states. Moods are often defined as being of longer duration than emotions without a clear trigger or object. The term affect is used throughout this chapter, rather

[☆] *Change History:* November 19. Sandra Russ updated the text throughout the article.

This article is an update of S.W. Russ, Emotion/Affect, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 449–455.

than emotion, because affect is the more inclusive concept. Affective processes refer to the different dimensions of affect, or types of affect events, that occur within the individual. Most theorists think that cognition frequently is involved in the affective processes, although they differ as to whether affect is always involved, the degree of involvement, and the type of involvement.

Types of Affective Processes

In 1993, Russ identified that affective processes have emerged that are important in creativity based on theory and the research literature. The five affective processes, briefly defined, are as follows:

1. **Openness to experiencing affect states.** This is the ability to feel the affects and specific emotions as they occur. Tellegen and others have found that different types of affect states can be classified as positive affect or negative affect. Individuals differ as to how much they can experience positive and negative affect states. These specific feeling states seem to function differently in the creative process.
2. **Access to affect-laden thoughts, images, and fantasy.** This is the ability to think about ideas, images, memories, and fantasies that include affect. Thoughts involving affect themes such as aggression, sex, affection, or anxiety illustrate this blending of affect and cognition. The psychoanalytic concept of primary process thinking, to be discussed in a later section, is an example of this type of affective process.
3. **Affective pleasure in challenge.** This process involves the excitement and tension that comes with identifying a problem or mystery and wanting to immerse oneself in the task. A combination of positive and negative affect could be involved.
4. **Affective pleasure in problem solving.** This is the tendency to take a deep pleasure in solving a problem or completing an artistic production.
5. **Cognitive integration and modulation of affect.** This is the ability to control, think about, and regulate the affective events one experiences and not be swept away. Although this process is probably more cognitive than affective, it warrants inclusion because it involves both cognition and affect and it is important in the creative process.

Three other types of affect systems important in creativity are often referred to as broad motivational systems. The whole area of motivation subsumes needs, drives, and affective processes. Drive refers to both primary and acquired drives. Three major motivational systems that have been found to be important to creativity and that include affective components are intrinsic motivation, curiosity, and conflict-resolution and self-expression.

6. **Intrinsic motivation.** This is the motivation that comes from within the individual to perform a task rather than coming from sources external to the individual, such as rewards or evaluation. Amabile has carried out a research program that has found intrinsic motivation to be especially important in creativity. Positive affect is an important part of intrinsic motivation, as Amabile and Hennessy have pointed out.
7. **Curiosity.** Curiosity is a motivational state found to be important in creativity. Berlyne has written extensively on this issue. He wrote in 1966 about his view of curiosity as reflecting the organism's striving to maintain an optimal level of arousal.
8. **Conflict-resolution and self-expression.** This is the motivation that comes from the need to resolve an internal conflict or distress or to express intense emotions. In the case of conflict-resolution, a psychoanalytic concept, the individual expresses emotion through creative outlets in an attempt to resolve the problem. Sublimation occurs if the personal conflict is channeled into a specific creative endeavor and is transformed into a more universal issue. In the case of self-expression, there are many anecdotal accounts of individuals using the arts as a form of therapy to deal with emotional problems or daily stresses.

These different affective processes and motivational states work in different ways in different areas of creativity and for different types of creativity tasks. As a field, we are just beginning to learn about the role of these processes.

Theories of Affect and Creativity

Different theories of affect and creativity focus on different types of affective processes and different types of creativity. There is no one comprehensive theory that accounts for all variables and all research findings.

Psychoanalytic Theory

Historically, the first theory of affect and creativity was psychoanalytic. The key concept in the area of psychoanalytic theory and creativity is primary process thinking.

Primary Process Thinking

Sigmund Freud in 1915 first conceptualized primary process thought as an early, primitive system of thought that was drive laden and not subject to rules of logic or oriented to reality. A good example of primary process thinking is the kind of thinking that occurs in dreams. Dreams are illogical, are not oriented to rules of time and space, and frequently include affect-laden content and images. Affect is a major component of primary process thinking. The content of primary process thought is frequently affect-laden content, such as sexual images or aggressive ideation. In children, affect-laden, primary process thinking frequently includes oral (good ice cream), oral aggression (biting Dracula), and aggression (fighting; bickering).

Access to primary process thought has been hypothesized to relate to creative thinking for several reasons. First, because associations are fluid and primitive images and ideas can be accessed and used, there is a wide range of associations to be used in creative work. According to classic psychoanalytic theory, primary process thinking is characterized by mobility of cathexis—that is, the energy behind ideas and images is easily displaced. In this mode of thinking, ideas are easily interchangeable and attention is widely and flexibly distributed. Therefore, access to primary process thinking should facilitate a fluidity of thought and flexibility of search among all ideas and associations. Flexibility and fluidity of thought are characteristic of two of the most important cognitive processes involved in creative thinking. Second, the affective component of primary process thinking should also be facilitative of creative thinking. Individuals who are comfortable with affective ideation should have a wider range of associations. In Freudian terms, they would be less “repressed” and be comfortable thinking about a wide range of affective content. This ability would be especially helpful in artistic expression in the arts. In the arts, especially the narrative arts, it is helpful to remember past events that include complex and uncomfortable emotions.

Divergent thinking and transformation abilities are the major processes that are unique to the creative process. Divergent thinking refers to the ability to generate a variety of associations to a word or solutions to a problem. A typical item on a divergent thinking test would be “How many uses for a brick can you think of?” A high scorer on this test would generate a high number of different, acceptable uses for the object. Individuals who can use primary process and the fluidity of thought and breadth of associations inherent in it should be highly divergent thinkers. They should also score high on a second important cognitive process, transformation ability. This involves the ability to transform or revise what one knows into new patterns or configurations and to be flexible and break out of an old set. Again, the broad associations and flexible thinking characteristic of primary process should facilitate transformation abilities.

Regression in the service of the ego. An important point in psychoanalytic theory is that it is controlled access to primary process thinking that is facilitative of creative thought. The concept of regression in the service of the ego postulates that creative individuals could regress in a controlled fashion and tap into primary process thinking. The creative individual could go back and forth between early, primitive primary process thought and more mature, rational, secondary process thinking. The creative individual could be distinguished from the individual with a thought disorder in that the creative individual was in charge of this regressive process and could critically and logically evaluate the loose, primitive associations and images.

A number of theorists have proposed that the concept of regression may not be necessary in understanding the relationship between primary process and creativity. Rather, we can think of primary process as a separate cognitive-affective process that one can have access to that then facilitates divergent thinking and transformation abilities. A separate ability to cognitively integrate and modulate primary process thinking would be important in the critical evaluation stage of creative thought. The ability to switch between affect-laden primary process thinking and logical critical thinking is associated with creativity.

In summary, the psychoanalytic model of primary process and regression in the service of the ego stresses the importance of two types of affective processes in creativity: a) access to affect-laden thoughts and images and b) cognitive integration of affective material. These processes are important in the facilitation of creative cognitive processes.

Empirical Evidence

Primary process has been found to relate to creative processes in the research literature. Most of the research has used the Rorschach inkblot test as a measure of primary process. In general, as psychoanalytic theory predicted, the ability to give good responses to the Rorschach that contained primary process content was significantly related to measures of divergent thinking and flexibility in problem solving. Using a different approach, good artists were found to have more primitive primary process content than poor artists and top ranked creative architects had more libidinal (sexual) primary process content than lower ranked architects.

Similar results have been found with children, although age, gender, and specific scores emerge as important factors. Primary process on the Rorschach significantly related to divergent thinking and to flexibility in problem solving for boys, but not for girls, independent of intelligence. These gender differences occur throughout the research literature with adults and with children. For children, much of the primary process responses on the Rorschach have affect themes in the percepts. Typical responses in children are bloody bears, scary monster, or yukky spider.

In summary, affect-laden primary process thinking is related to cognitive processes important to creativity for males. For females, the results are mixed. A few studies found that pure access to primary process was related to creativity in females. One possible explanation for these sex differences is that females do not have as much access to primary process thought because of cultural taboos and socialization processes. Another explanation could be that the Rorschach is a more valid measure of primary process for males than for females. Indeed, when measuring primary process in children’s play, Russ found that primary process related to divergent thinking for both boys and girls. There are many questions remaining to be answered in this research area.

Conflict-Resolution and Self-Expression

From a different perspective, psychoanalytic theory has stressed the importance of unresolved conflicts and unfulfilled wishes in motivating the individual to engage in creative work. For example, unrequited love will be expressed in a poem or drawing. Resolving the loss of a loved one will occur as a result of composing a song. The motivating force of transforming one’s own pain into artistic creations that have universal appeal is thought to be an important factor in creative work. Although there is little direct empirical evidence for this theory, there is indirect evidence from clinical vignettes from therapists and from descriptions from creative individuals. In addition, Pennebaker’s research found that expressive writing can have beneficial effects on mental and physical health.

Mood and Creativity

Research has investigated very specifically how affect influences cognitive processes important in creativity. Much of the research within this framework has used a mood induction paradigm. A specific mood state is induced by having participants watch a film, receive a gift, or think about a memory that is happy or sad. Mood induction provides a way of altering affect states so that the effect on cognitive processes can be observed.

A growing body of research has found that induced affect facilitates creative thinking. [Alice Isen \(1987\)](#) has carried out a series of important, carefully controlled studies in the mood induction area. She and her colleagues found that positive affect induction resulted in more creative problem solving when compared to control groups. Other researchers found similar results with a variety of creativity measures. Isen concluded that the underlying mechanism is that positive affect cues positive memories and a large amount of cognitive and affective content. This process results in defocused attention and a more complex cognitive context. This, in turn, results in a greater range of associations and interpretations.

What about negative affect? In general, induced negative affect has had no effect on creative problem solving. As the researchers pointed out, it is possible that the negative affect that was aroused (for example, by a film of the Holocaust) was too extreme, and that less extreme conditions of negative affect should be explored. A few studies suggest that milder forms of negative affect could facilitate some kinds of problem solving tasks. Different types of affect may have different effects on various dimensions of problem solving ([Kaufmann and Vosburg, 2002](#)).

In a recent meta-analysis of 25 years of mood-creativity research, [Baas, de Dreu, and Nijstad, \(2008\)](#) concluded that a number of variables are involved in this complex area of mood and creativity. Specific mood types (not just positive and negative) and aspects of those moods must be considered. They concluded that positive moods do produce more creativity than neutral moods. But this is true for positive moods like happiness that are activating and associated with approach motivation. It is not true for positive but deactivating mood states like relaxation. They point out that an interesting practical implication of this finding is that relaxing in a bathtub or on the beach may not be conducive to creative thinking. How the task is framed is also important. Positive moods lead to more creativity when the task is framed as enjoyable and intrinsically rewarding and to less creativity when the task is framed as serious and extrinsically rewarding. As for negative affect, in general, deactivating negative mood states like sadness were not associated with creativity, but activating mood states of anger, and in some situations, fear, were facilitative. Baas in [2019](#) concluded that valence, activation, and motivation activation are all involved in determining mood effects on creativity.

Intrinsic Motivation

Intrinsic motivation is conducive to creativity. Intrinsic motivation is defined as having to do with the intrinsic value of attaining a creative solution. Research has found that conditions extrinsic to the task, such as reward, evaluation, being watched, and restricted choice, all have detrimental effects on creativity. Intrinsic motivation is important for task persistence, for seeing a project through, and for ensuring exploration of solutions.

Intrinsic motivation is also accompanied by positive affect. The love of the task is an important component of creative work. Love of the work has been mentioned as crucial by most creative individuals. More research is necessary to explore the positive affect and intrinsic motivation link.

Tension and Creativity

Tension as an important factor in creativity has been conceptualized by Mark [Runco \(1994\)](#). He presented a variety of ways in which tension could be involved in the creative process. The anticipation of the resolution of tension could be an important motivating force in creative problem solving. The tension could be an internal conflict, similar to psychoanalytic theory's idea of conflict-resolution. For example, several researchers have found that creative individuals have come from families with problems or have themselves felt marginalized in the society. Tension could also develop from identifying a problem or sensing a gap in an area. Problem identification is important in creativity. Creative individuals could use the tension experienced in seeing the problem as both a cue and a motivator. Tension can also be conceptualized as an activation mood, as discussed above.

Affective pleasure in challenge could also be part of this process. There could be a mix of negative (tension) and positive affect in identifying a problem. The anticipation of the positive affect involved in solving the problem may act as a motivating force. However, there may be an inherent excitement in seeing the ambiguity in the situation that leads to problem identification, which is itself pleasurable. It may be similar to the pleasure that some children feel in discovering "What is wrong with this picture?"

The concept of optimal challenge is relevant here. An optimal amount of challenge is necessary for the experience of flow to occur. Flow is a total involvement in the activity, a deep sense of enjoyment, and optimal challenge. Creative activities involve this sense of flow. Perhaps optimal challenge involves the best mix of tension in seeing the problem and the anticipated pleasure of the creative act.

Curiosity

Although it is not clear whether or not curiosity has affective components beyond arousal, it is a motivational system important in creativity. Curiosity may be viewed as reflecting the organism's efforts to maintain an optimal level of arousal. Subjective feelings of

pleasantness have been associated with the growth of the curiosity drive as a function of increasing stimulus intensity and arousal of the positive reward system. Curiosity may interact with anxiety to determine approach or avoidance behavior.

Curiosity is important to creativity because interest in novelty and exploration aids in problem identification as well as task persistence. Also, the highly curious and risk-taking individual is more likely to gain a wide variety of experience that would add to his or her knowledge base.

Integrative Models of Affect and Creativity

Integrative models of affect and creativity identified the connections among affect, cognitive, and personality processes important to the creative process.

In the 1993 Russ model of affect and creativity, the major cognitive abilities that emerge as unique to and important in the creative process are linked to related specific affective processes and to global personality traits. In some cases, the personality traits are behavioral reflections of the underlying affective processes. One assumption of this model is that these specific affective processes and personality traits facilitate creative cognitive abilities. Reciprocal interactions probably occur as well.

Because there is no one comprehensive theory of affect and creativity, a variety of theories and underlying mechanisms are represented in this model. At this time, it appears that different mechanisms underlie different components of the creative processes. For example, access to affect themes and affect states facilitates a breadth of associations. Intrinsic motivation should help the individual keep on task and explore alternative solutions. Good cognitive integration of affect should aid the critical thinking process necessary in the evaluation stage of creative work. An important point is that in any creative act, different processes and different mechanisms could be involved.

Ivcevic and Hoffman (2019) present a comprehensive model of creativity and emotions. They focus on emotion-related personality traits and emotion abilities such as the ability to manage emotions and to use emotions in creative thinking.

Play, Affect, and Creativity

Play is important in the development of many of the cognitive, affective, and personality processes important in creativity. The type of play most important to the area of creativity is pretend play. Pretend play involves make-believe, the use of fantasy, and treating one thing as if it were something else. Pretend play frequently involves affect. Children express both positive and negative emotion in play. In 1987, Fein proposed that the affect is represented in an affective symbol system. Information about affect-laden events and relationships is coded and stored in these symbols. These symbols are reflected in pretend play and are especially important for creative thinking. From a psychoanalytic perspective, play is a place where primary process thinking as well as other kinds of affect can be expressed.

Research Evidence

Research supports a relationship between affect in play and creative thinking that is independent of intelligence. A positive relationship has been found between playfulness (that included the affective components of spontaneity and joy) and divergent thinking in kindergarten children. Similarly, a relationship has been found between the amount of affect expressed in play and divergent thinking in several samples of first and second graders and in preschool children as well. In a longitudinal study, affect in play in young children predicted affect in play stories in older children. This longitudinal study suggests that affect in fantasy is a trait that has some stability over a four year period.

It is important to note that both positive and negative affect in play relate to creativity. In play, negative affect is well-controlled in most children and is pretend, after all. The negative affect is not intense and is often enjoyable to the child.

Affect in play has also been found to be associated with affect in memories. Having access to emotional memories could also be an advantage in creative production.

Play has been found to facilitate creativity in children, but there is no conclusive evidence that it is the affect expression in play that is the causative factor. That question continues to be investigated.

Affect, Creativity, Adjustment, and Psychopathology

Research has found that creativity relates to both adjustment and psychopathology. How can both findings be true? If we conceptualize creativity as evolving from a configuration of cognitive, affective, and personality processes that set the stage for creative acts to occur, then the propensity for adjustment could go either way depending upon the mix of processes. If creative individuals are good divergent thinkers, have diverse associations, have access to primary process in a controlled fashion, are open to affect states, and are good critical thinkers, then one would expect them to be sensitive but relatively stable individuals, perhaps with periods of emotional instability. Some research studies are supportive of the hypothesis that creative individuals are adaptive and well-adjusted. Many of the psychological traits that are related to creativity are also indicators of positive mental health.

Other researchers have found a relationship between creativity and psychopathology. In a study of British artists and writers, 38% of the sample sought treatment for mood disorders. [Ruth Richards \(1993\)](#), based on her research, offered three major conclusions about creativity and mental health. She concluded a) mild psychopathology may contribute to creativity (mild mood swings especially may carry advantages for creativity), b) intermediate levels of variables may be most optimal for creativity, and c) affect is important in creativity. She stressed the importance of positive affect for creative accomplishment.

Artistic and Scientific Creativity

Affective processes play different roles in different domains of creativity. In general, scientists have been found to be better adjusted than artists. A higher than normal proportion of artists have been found to have mood disorders. Research with scientists paints a different picture. A number of researchers have concluded that creative scientists may be a more emotionally stable group than creative artists. Why would this be so? The personality differences between creative artists and scientists may reflect the differences in the domains of creativity and the cognitive and affective processes that are involved. There are similarities. Divergent thinking is important in scientific problem solving as well as in artistic production. Breaking out of a set and creating new configurations are also important in both types of creativity. Affective process would be expected to function in similar ways for similar creative tasks in artists and scientists.

One of the main differences between artistic and scientific creativity may be the importance of getting more deeply into affect states and thematic material in artistic creativity. This in-depth involvement in the affective processes themselves may not be as necessary in scientific problem solving. Some theorists think that artists incorporate early traumas and conflicts into their artistic productions. Scientists do not usually have to face into and incorporate affect-laden material into their scientific problem solving. For the scientist, good divergent thinking ability, transformation ability, and a flexible cognitive style may be sufficient for creative work to occur. For the writer, the musician, or the artist, the need to get to basic and deep emotions, primary process material, and affect-laden memories and images may be necessary in order to be able to express universal truths that transcend the individual and speak to others.

One often hears artists and writers describe the need to have this kind of experience. One can see how the need to live in that emotional state and to control that process may at times be disruptive, resulting in emotional instability and some personal agony. Writers in particular describe anxiety at uncovering primary process material.

On the other hand, interviews with creative scientists indicate that scientists often feel very strong emotions during the creative process. In a study that gave artistic and scientific problems to art and science students and had them rate their intensity of emotions, art and science students experienced the same intensity of affect before and during insight, but art students reported more positive emotion after insight than did science students.

It is logical to assume that each specific artistic and scientific domain will have cognitive and affective processes that are especially important in that area. Different creative profiles should emerge for different fields. A dynamic (not static) mode of affective-cognitive interaction has been proposed for artistic creativity. Creativity and psychopathology are ever changing continua with a mixture of affect states. Only a dynamic model can capture the complexities of the interactions.

Neurological Processes, Affect, and Creativity

As research on affect and neurological processes becomes more sophisticated, neuroscientists are learning about the interaction between affect and cognition. With the development of the CAT scan, PET technology, and fMRI technology, researchers can map cerebral activity and obtain a picture of brain involvement during problem solving. Eventually, images may map the actual neurological processes involved in creative problem solving.

Research by Klaus Hoppe showed that the mutual interaction of the left and right hemisphere is important in creativity. The corpus callosum is involved in exchanging information between the hemispheres. The symbolization and visual imagery in the right hemisphere is available to the left hemisphere in creative functioning. Cognitive representation of emotion occurs in both hemispheres.

Research on the neurological processes involved in affect processes has addressed several important questions in the area of emotion that have implications for the affect and creativity area. It has been concluded that different emotions have different neurological and physiological activity. It appears there are different brain systems that mediate different emotions. Therefore, researchers need to investigate specific emotions. This conclusion is consistent with the findings in the affect and creativity area that different emotions have different effects on cognitive processes.

It has also been proposed that different emotions are represented in memory. An important point is that these emotions appear to be stored in the amygdala. This is a different area of the brain than that which stores non-emotional memories, the hippocampus. Research suggests that emotional memories are organized differently than are non-emotional memories. The emotional memory can act independently of the cognitive system. It has been suggested that these precognitive emotions are functional in infants during the early formative years. Behavior is affected, but the individual has no conscious memory of the event.

The concept of emotional memories functioning as a separate system is consistent with some theoretical explanations about why affect should facilitate creativity. If affect stirs a network of associations and emotion-laden memories, which in turn affects cognitive processes, then the organizational system of those emotional memories becomes very important. The rules that govern how this

emotional memory system functions still await discovery. These principles should help understanding of the mechanisms that underlie the complex relationship between affect and creativity.

Conclusion

During the past 30 years, there has been a resurgence of research in the affect and creativity area. As it should be in any science, the research is theory driven; theories are being developed and tested, measures and methods are being refined, and new lines of investigation are opening. The field is interdisciplinary and what is learned in one field informs another. For example, knowledge about affective processes from neurophysiological research will be applied to affect and creativity research. Key concerns for the future in the affect and creativity area are a) identifying specific affective processes that are most important for creativity tasks; b) discovering the underlying mechanisms that account for the relationships between affect and creativity; c) exploring differential effects of various types of affect, such as positive or negative affect, on creativity; d) understanding how affect and creativity relate to psychological adjustment and psychopathology; and e) understanding the developmental processes involved in affect and creativity. As research paradigms and measures of affect continue to be developed, researchers will continue to learn about this exciting area.

Introduction

Plumbers solve plumbing problems; Accountants solve financial problems; Doctors solve medical problems—and Engineers solve technological problems. The point of this is that most professions can be described succinctly as exercises in generating solutions to problems. In many cases, the solutions represent the reapplication of some tried and tested concept. For example, each morning as we secure our shoes to our feet, we do not need to reinvent shoelaces. These simple bits of string serve their purpose, and are a satisfactory solution to the underlying problem.

However, in many cases, the tried and tested solution is not enough. What if cotton, or nylon, were no longer available; or perhaps Government imposed a heavy tariff on these materials? Would our conventional shoelace still be a viable solution to the problem? What happens when the plumber encounters, for example, a house that draws water from a private well instead of from a municipal water supply? How does a doctor diagnose a patient who is too young to describe their symptoms?

Each of the preceding examples represents the impact of *change* on an otherwise routine problem solving process. Change brings with it one of two requirements. Either, the solution must be an *incremental improvement* on what already exists—it must be better, or faster, or cheaper—or, it must be a *wholly new* concept—a paradigm shift, in other words.

Take the case of climate change, and in particular, the problem of carbon added to the atmosphere as a result of coal-fired power generation. The *change* to the climate means that the solution to energy generation—burning coal—is no longer a viable, or sustainable, solution. It's true that one possible solution is to continue to burn coal. However, as Albert Einstein warned, doing the same thing over and over again, and expecting a different result, is insanity (and self-evidently, will not reduce carbon in the atmosphere). This means that only two realistic solution pathways exist. Either, make incremental improvements to the existing solution, for example by making coal-fired power generation *cleaner*, or, find a wholly new approach to the problem of power generation, such as solar-thermal or wind-powered electricity generation. The former—clean coal—is an incremental approach to an existing problem, while the latter is a completely new, or radical, approach.

Because *change* is such a ubiquitous, perhaps even defining, characteristic of life on this planet, it is no surprise that a key feature of most professions—not least engineering—is the ability to generate both incrementally, and radically, *new* solutions. In other words, a key concern of engineering is the generation of new and effective solutions to problems—that is, *creativity*!

Engineering and the Psychology of Creativity

A strong case can be made (e.g. Cropley, 2015) that it was engineering that served as the catalyst for the modern interest in creativity. The *Sputnik Shock* of October 1957 – the launch of the world's first artificial satellite—galvanised the United States and other Western nations, and for the first time linked technology and creativity together. How was it possible for the Soviet Union to beat the United States in the first major event of the Space Race? As the United States grappled with this fact, creativity was offered as one explanation for the success of the Soviet Union's satellite technology. What this meant was that for the first time, a *psychological*, qualitative explanation was put forward to explain a technological, quantitative achievement. Western thinkers attempted to explain the Soviet breakthrough not just in terms of resources and technology, but in terms of *who* developed the new technology, *how* and *why* they developed it, and *where* the development of the technology took place. The Soviet achievement in space, rightly or wrongly, was attributed to superior *engineering creativity*! Fortunately, the means to explore this hypothesis further had been set in motion by Guilford (1950), and his early work on the psychological concept of creativity.

In fact, throughout human history, people have been developing technological solutions to problems stemming from basic driving *needs* (in the sense of Maslow, 1943: for food, warmth, shelter, security, and so forth) and problems stemming from *change* (to their environment, and to their resources). The need to develop more efficient ways of providing food led to the development of the pre-historic hand axe. The need to propel watercraft more efficiently led to the development of the oar. The need to spin natural fibres into thread and yarn, in order to make cloth, led to the development of the spinning wheel (see Crompton, 2019 for a full discussion of the history of technological creativity). The psychological capacity to generate and exploit novel, effective solutions to technological problems—*engineering creativity*, in other words—has been an abiding strength of the human species for thousands of years.

Engineering Design: Creativity

The *process* of generating new and effective solutions to problems, if not the broader psychological elements, has long been understood as central to engineering. Indeed, "... if more than one solution exists, and if deciding on a suitable path demands ... making choices, performing tests, iterating, and evaluating, then the activity is most certainly design" (Horenstein, 2002, p. 23). There is, therefore, a remarkable similarity between what Guilford (1959) identified as the key stages of creative problem solving—problem recognition, idea generation, idea evaluation, and solution validation—and the key steps of engineering design.

The core elements of this creative, design process hinge on two forms of thinking. On the one hand, the ability to recognise that a problem exists, and to express it concisely and accurately, requires the ability to think *convergently*. The ability to apply logic and analysis in order to find the *right* answer is critical. Similarly, the ability to evaluate the relative merits of a range of possible solutions, usually against a set of constraints, is a convergent process. Even once a particular possible solution has been selected, verifying that it does, indeed, satisfy the underlying problem remains a process of logic, analysis, evaluation and judgement.

Where engineering design has frequently lagged behind creativity, however, is the key stage involving the generation of the *possible* solutions. This *divergent* thinking stage, almost synonymous with the modern concepts of creativity, requires unconventionality, an ability to shift perspective, and a capacity to introduce new, often surprising, ideas. Without divergent thinking, neither creativity, nor engineering design is capable of responding to needs and to change with incrementally and radically new solutions.

In many ways, therefore, engineering design is the ultimate expression of creativity. For thousands of years humankind has depended on its ability to recognise problems, generate a diverse range of ideas for solving those problems, and the ability to evaluate and implement these ideas as practical solutions. This would seem to suggest that humankind, in the process of engineering design, has reached a pinnacle of creativity.

Notwithstanding considerable evidence to support such a claim—modern farming technologies that feed billions; modern medical technologies that have cured diseases, and; modern communications technologies that connect people across the globe—there remains enormous scope for improvement. The engineering profession remains one that is seen principally in terms of the application of critical thinking skills, and the laws of nature, to the efficient use of raw materials. Engineering design is seen more as a matter of reapplying the *known*, rather than as a question of exploring the *new*.

Engineering design is a good representation of creativity, but it is not yet the *optimal* representation of creativity. Not only are there weaknesses in parts of the *process*, in particular the application of divergent thinking, but there are also opportunities to improve engineering design by drawing on the considerable body of knowledge available from some 70 years of, largely psychological, creativity research. To move towards this optimisation of engineering design as an expression of creativity, at least five questions need to be addressed. These hark back to the turmoil surrounding the Sputnik Shock, and the search for a qualitative answer to that event. These questions are:

- *Who are the creative engineers?* What aspects of motivation, personality and affect define the creative engineer? Are these essentially the same as creativity in any domain?
- *How do creative engineers think?* Exactly how do engineers make use of convergent and divergent thinking? What does each type of thinking contribute to the design process?
- *What is a creative engineering environment?* What factors in a typical engineering workplace can help or hinder creativity? How best is the ideal engineering design environment created?
- *How do we recognise creative artefacts?* What characteristics define a creative product? Is creativity more than just novelty? What value is added by creativity in a solution?
- *How should creative engineers be educated?* Is engineering education teaching things right? Is engineering education teaching the right things? How can engineering education be rebalanced for optimal creativity? What is the impact of the future of work on engineering education?

Key Concerns for Creativity in Engineering

As the United States, in particular, responded to events in the Space Race during the late 1950s and early 1960s, it looked as though engineering was entering a Golden Age. Massive investments in STEM education, and Kennedy's challenge of landing humans on the Moon, coupled with a new, cross-disciplinary interest in the psychology of creativity, seemed to herald an era in which engineering design would incorporate, on an equal footing, all of the elements that are a necessary part of Guilford's

(1959) stages of problem solving. Buhl (1960) is a particularly good example of how this cross-disciplinary thinking was developing during this period.

That these questions are still being raised in the 21st century may be partly a result of success of the United States in the Space Race. Only 12 years after the Sputnik Shock, the US succeeded in landing humans on the Moon, and the panic of 1957 had subsided. Perhaps all that was required, after all, was *quantity*? With more engineers, more resources, and more money, any technological problem could be solved with a kind of quantitative *brute force*. And yet, as the world moves rapidly into the era of Industry 4.0, big data, artificial intelligence, and cyber-physical systems, attention is turning, once again, to qualitative questions of engineering, design and the future of work. The following sections summarise five questions that have always demanded answers, if engineering design is to fulfil its potential. However, in the current era of digital transformation, these questions may be more important than ever before.

Who Are Creative Engineers?

For some 70 years, psychologists have examined the facets of personality and qualities of the individual that link to creativity. Even though one of the abiding debates in creativity research concerns domain-general and domain-specificity—is creativity a general characteristic or quality, or is it unique to different domains—there seems to be wide agreement that Openness to Experience (in the sense of personality) is characteristic of all creative individuals, and therefore engineers. Conscientiousness also features prominently as a strength of creative individuals in domains that lie towards the scientific end of the Art versus Science continuum.

In addition to high levels of openness and conscientiousness, creative engineers would also be expected to be goal-directed, willing to ask questions and to take risks. Furthermore, in terms of affect—feelings and emotions—creative individuals, including engineers, would be expected to show flexibility, curiosity, tolerance of uncertainty and independence.

On the one hand, it seems possible, based on extant research, to formulate a fairly clear answer to the question *who are creative engineers*. At the same time, domain-based studies frequently use categories—Art and Science, for example—that do not do justice to the nuances *within* the domain.

Even within a domain such as *science*, there are large differences between, for example, engineering and industrial design. Both are concerned with the development of artefacts, and both are broadly technological in nature. Both seek to satisfy needs typically expressed by end-users, and yet engineering can be said to approach such problems from the *inside out*, while industrial design works from the *outside in*. Cropley and Kaufman (2019) examined differences between these two groups in order to expose more subtle *within-domain* differences. If engineering design, as an expression of creative problem solving, is to be optimised, then a deeper, and more domain-specific, understanding of personality, motivation and affect is needed. Is engineering design attracting people with the right dispositions, and is the domain shaping these dispositions in a way that maximises the opportunity for creativity? Is one general disposition right for engineering design, or is the key the ability to switch back and forth, much like the creative problem solver must switch between convergent and divergent thinking as the process unfolds?

How Do Creative Engineers Think?

Guilford's (1959) model of the creative problem solving stages is noteworthy, in particular, for how it identifies the two key cognitive processes: convergent and divergent thinking. The former is defined by logic, analysis, and the ability to find a single, correct, solution. Divergent thinking, in contrast, is characterised as a process of generating many possible solutions, without regard to constraints such as correctness. Each is necessary, but not sufficient, for the overall problem solving process. Almost by tradition, it is assumed that engineering is largely concerned with convergent, critical thinking.

Discussions of engineering do, in fact, identify a generative, divergent stage as central to design. Despite this, it is rare to find discussions of engineering design drawing on the psychological literature of divergent thinking to optimise this part of design. An explanation for this disconnect may lie in how psychologists have defined, and measured, divergent thinking.

In traditional, psychological discussions of divergent thinking, this cognitive process is typically measured by presenting an individual with an object—a brick, for example—and inviting the individual to respond with as many *alternate uses* as possible for that object. Divergent thinking is measured in terms of the volume and nature of the alternate uses generated. Cropley et al. (2017), however, noted that this *form-first* approach to divergent thinking—presenting a *solution* (a brick) and asking for as many *problems* as possible (how to build a house, how to hammer in a nail, etc) – while undoubtedly divergent, is not how engineers work or think! They suggested that a realistic form of divergent thinking, at least for engineers, is *function-first* in nature. In this case, the stimulus is a *problem*—e.g. how to build a house—and the responses are a variety of possible solutions—e.g. bricks, rocks, wood, etc. It may be that when engineers search for help to optimise the creative design process, and find the key stage of idea generation characterised as a form-first process, they ignore this as irrelevant to their needs and look elsewhere for help.

Like any creative, problem solving, process engineers think in two ways. They must think convergently in order to identify and refine the problem to be solved. In engineering, good practice is to express this problem in just four words—*how to verb noun*—where the verb and the noun are expressed in as abstract a form as possible, so as not to constrain possible solutions. Equipped with a well-defined (and function-first) problem statement, engineers must then switch to a divergent thinking style to generate possible solutions, without regard to quality or feasibility. Once this pool of possible solutions has been developed, logic, reason and analysis return with a convergent evaluation of the possible solutions. Now they must be evaluated for feasibility. Do they fit the constraints

of the problem? Finally, once the best solution has been selected, it must be implemented and evaluated. The final convergent question in a process of engineering design is *validation*. Does the solution do what it is supposed to do?

What Is a Creative Engineering Environment?

Engineers typically work in teams, such is the nature, scale, and the complexity of modern design and implementation processes in technology. Inevitably, therefore, the individuals (who) and the processes (how) intersect with an environment (where).

In fact, there has long been some recognition of this interplay between person, process and environment in engineering design. Defence and aerospace company Lockheed Martin created their famous *Skunk Works* in 1943 specifically to facilitate innovation through small, empowered teams. Founder Clarence “Kelly” Johnson sought to create an unconventional physical and organisational environment that removed bureaucratic barriers, defining 14 *rules and practices* of Skunk Works. These enshrined a simpler process, using small teams with high levels of authority and freedom, as well as a more flexible system of rewards.

In the 21st century, the psychology of creativity can explain why the Skunk Works environment is necessary for optimising engineering design. Cropley (2016) described this in a more generalised fashion. As the engineering design, creative problem solving process unfolds, it is governed by a series of either convergent or divergent stages. Individuals engaged in this process are shaped by their individual dispositions, feelings and motivations. Each stage, in addition, may be facilitated, or constrained by general environmental conditions. In this way, each stage of engineering design, to be optimised, requires the right set of individual dispositions and qualities, coupled with the right environmental conditions for the particular convergent or divergent stage in question. If any of these three are misaligned—for example, an unmotivated, closed individual in a divergent thinking process, or, a highly motivated, highly divergent team, with no time or resources to generate ideas—then engineering design, and creativity, will be blocked.

Where many modern engineering organisations struggle, in the engineering design process, is with a lack of organisational, cultural flexibility. In an organisational context, engineering design is a matter of aligning people, processes and culture. Most engineering organisation have a natural, or default, combination of these factors. Sometimes these naturally align with the conditions that are ideal for design and creativity, but often there is a mismatch. For many engineering organisations, this default combination favours problem recognition, idea evaluation and solution validation, but blocks idea generation. These organisations are good at implementing a solution once they have it, but struggle (and often *know* they struggle) in getting the good solution in the first place. The pathway for optimising engineering design, for these firms, lies in developing their agility—their ability to recognise each stage of the process as they are in it, and to tune their environment and people to suit.

How Do We Recognise Creative Artefacts?

The purpose of engineering design, and creativity, is to generate solutions. Processes, employed by individuals, in organisations lead to the generation of a variety of solutions of a broadly technological nature. Two issues, however, have limited engineering design creativity. What *are* solutions, and what does a creative solution *look like*?

Solutions to engineering problems can take one of four broad forms. *Artefacts* describe tangible objects such as cell phones and chairs—more broadly, hardware—that can be touched and observed. *Processes* describe activities or tasks, possibly executed by people, which achieve an outcome. *Systems* describe more complex combinations of hardware, software, and people that satisfy defined needs. *Services*, finally, describe usually intangible systems of labour and/or material aids that achieve some outcome.

Even with the range of solution types defined, many engineering organisations still struggle with the fundamental question of what does a creative solution look like? What properties or characteristics define creativity in a solution, and what value do they add?

There is good agreement in the creativity research literature regarding two key qualities of a creative solution. Novelty is a prerequisite. If a solution is not new, original, and surprising, then it cannot be regarded as creative. A creative solution must also be appropriate to the task, or problem, in question. Cropley and Cropley (2005) first discussed these properties of a creative solution in an engineering context, reaffirming that *novelty* and *effectiveness* must be present in a *creative* solution. Extending this discussing specific to the engineering domain, they also explained that *elegance*—in simple terms, how well executed a solution is—and *genesis* (the extent to which a solution changes the paradigm) also add to the creativity of a solution.

The value of effectiveness almost needs no explanation. A solution that is ineffective is, in fact, no solution at all. A solution that adds novelty to effectiveness moves a solution from the status of *an existing solution to an existing problem*, to a new solution to an existing problem. This incremental creativity—doing something better, or faster, or cheaper—injects the newness that is vital as a response to change. An elegant solution—one that is well-executed—is usually also a more effective solution therefore enhancing the overall creativity of the solution. Finally, when a solution possesses genesis we often find solutions that have redefined the problem. A solution with genesis is not just an existing solution that is improved, but is a wholly new concept. Incremental solutions have a finite life, governed by the law of diminishing returns. Genesis is the means for defeating the law of diminishing returns, by introducing wholly new concepts.

How Should Creative Engineers Be Educated?

Despite the centrality of design to engineering, and therefore the importance of creativity as a part of engineering, there remain many opportunities to align this creativity with engineering. The discipline of engineering has demonstrated many great

achievements in creative problem solving over many centuries. And yet, there remain many areas ripe for optimisation through a greater understanding of the psychology of creativity amongst engineers.

One particular area of engineering that is overdue for innovation is education. Many institutions, and many professional bodies, have paid lip service to creativity over many years, with little real change to curricula. Cropley (2017) has discussed the problems, and possible solutions, in greater detail. A long-standing reductionist paradigm in engineering education has resulted, for decades, in engineering curricula whose primary focus seems to be narrow over-specialisation and an emphasis on factual, as opposed to practical, knowledge. Very little room is made for the deliberate development of skills and abilities vital for design and creative problem solving.

There is some reason for optimism, however, with a growing awareness of the necessity for creativity and complex problem solving skills in a world dominated by digital transformation, Industry 4.0 and related technologies. The psychologist Jerome Bruner (1962), in fact, warned of the coming change describing a future in which creativity would be the last bastion of human mental sovereignty. This is as true of engineering as of any activity. Engineering education must be proactive in leading the transformation of engineering to a focus on design and creativity.

Creativity in Other Domains?

The field of creativity continues to debate questions of domain-generalty/specificity (e.g. Kaufman et al., 2017). There is broad consensus, for example, that an individual, highly open to new experiences, motivated and with an appetite for risk, working in a favourable environment, and equipped with the ability to think divergently, will exhibit creativity, whether artist, thief, or engineer. Research, however, continues to explore the nature and extent of domain-specific abilities. A creative artist, for example, may also be characterised by a *lack* of conscientiousness, in contrast to a creative engineer who is high on this trait. What seems to be settled is that the domain similarities and differences remain a function of four fundamental areas: person, process, press (environment) and product.

The point is that creativity is fundamentally the same thing across domains, and that is defined by the *stages* that govern this process. *Design* is just another term for the sequence of activities that comprise creative problem solving. Whether these steps are labelled as problem definition, problem recognition, idea generation, and so forth, or simply *what are you trying to do, how will you do it, and why is this way of doing it best*, there is an underlying similarity that links all creative domains. *Artistic design*, therefore, has much in common with engineering design, and the domain specific differences may be said to exist only when we dig deep enough. *There is more that unites creativity than divides it*, to paraphrase Argentinian statesman Mauricio Macri. If engineering is the ultimate expression of creativity, it is not because it is more worthy, but simply because it served humanity so well for thousands of years.

Concluding Thoughts

When engineering design is viewed through the lens of creativity research, certain things are apparent. First, the *process* of engineering design bears a strong similarity to the more general process of creativity. However, while creativity research has articulated many of the key psychological cognitive, personal and organisational concepts, features and characteristics of this process, engineering design has largely ignored these. Instead, engineering design, and engineering more broadly, has remained defined largely in terms of key processes of logic, analysis and judgement. Despite this narrow focus, history is replete with examples of humankind's skill in developing novel, effective, elegant and frequently paradigm-breaking solutions to all manner of needs and technological problems. As the world moves into an era of Industry 4.0, our ability to continue to exercise engineering creativity is more important than ever before. If we are to meet the challenges of climate change, economic change, and social change, it is time to refocus engineering creativity—to optimise it—to ensure that humankind remains adept at responding, with technological solutions, to the constant change that surrounds us.

Glossary

Canalization A concept from genetics and development research in which an individual's development is influenced by the environment within genetically determined boundaries.

Cognitive processes Actions taken by the human mind to detect, interpret, and manipulate information. These include attention, perception, rehearsal, and encoding, as well as higher-order thinking skills such as problem solving.

Constructivism Learning and cognitive theories that posit that knowledge is constructed, either individually or by groups.

Discretion Decisions about what to do and when to do it, and what not to do.

Functional fixedness Reliance on traditional techniques and strategies for problem solving, even when conditions surrounding problem diverge considerably from previously encountered conditions. The inability to consider alternatives when faced with problems, especially alternative uses for traditional problem-solving tools.

Information stores In the traditional model of information processing, the locations where information is stored either temporarily (working memory) or permanently (long-term memory).

Metacognition An individual's analysis of his or her own cognitive processes or, more colloquially, thinking about one's own thinking.

Rigidity Lack of flexibility in the application of cognitive processes, especially when problem solving. This inflexibility is reinforced by the effects of prior experience.

Schema Organized information found in long-term memory. Schema theory posits that more complex schema are associated with more efficient recall and information processing.

Self-efficacy Belief in one's own ability. Usually applied to a specific subject area or task, such as mathematical or reading self-efficacy.

Social constructivism Subset of constructivist learning theories that represent knowledge as being socially constructed, either

Can Creativity Be Enhanced?

In the not-so-distant past, the belief that creativity could not be enhanced was widespread. This notion about the unchanging nature of creativity could be found in academic circles as well as the media and popular press. Although perceptions have changed slightly over the past 40 years, a great deal of controversy still surrounds the nature and nurture of creativity.

The relationship between nature (inheritance) and nurture (experience) is best conceptualized as a continuum and not as an either-or proposition. Those holding a radical nativist view assume that creativity cannot be enhanced. The extreme nativist view is now rare and current consensus holds that potentials can be fulfilled and maximized, a concept referred to as canalization

[☆] *Change History:* July 2019. Jonathan Plucker updated the text throughout.

This article is an update of J.A. Plucker, M.A. Runco, C.B. Hegarty, Enhancement of Creativity, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 456–460.

in psychology and genetics research. The situation is analogous to one's height: each of us inherits a range of reaction within which our experiences have their impact. One person might inherit a range of potential height between 5 foot 6 inches and 5 foot 9 inches, and given specific developmental experiences (e.g., exercise, vitamins), grow to 5 foot 10 inches. This idea about a range of potential also applies to psychological constructs such as creativity and intelligence. Hence, in response to the question "Can creativity be enhanced?" the best answer is yes, because potentials can be fulfilled. Efforts to enhance creativity will not expand one's in-born potentials but can ensure that potentials are maximized.

The broad range of definitions of creativity frequently confuses discussions about creative enhancement. For example, if one defines creativity as divergent thinking, and another person defines it as both divergent and convergent thinking, the associated approaches to enhancement will likely be quite different. For the purposes of this entry, we use the comprehensive definition proposed by Plucker, Beghetto, and Dow, which encompasses most definitions and conceptions of creativity: "the interaction among aptitude, process, and environment by which an individual or group produces a perceptible product that is both novel and useful as defined within a social context."

What Exactly Can Be Enhanced?

When an attempt is made to enhance creativity, what exactly is the focus? To answer this question, the multifaceted nature of creativity must be recognized with its cognitive, affective, attitudinal, biological, interpersonal, and environmental components. Taken both collectively and individually, these aspects of creativity suggest targets for enhancement efforts.

Recent theory and research support the inclusion of diverse components in models of creativity. Each component has separately been the subject of significant theoretical and empirical investigation, but the importance of collectively considering these aspects is reinforced by the recent predominance of systems as well as interactionist and interdisciplinary theories of creativity. That said, we begin by discussing enhancement by focusing on each of the components.

Cognitive Components

Cognitive components are by definition intellectual. They reflect information-processing models and problem solving. Models of information processing generally include cognitive processes, transfer operations, information stores, and metacognition, each of which is important to consider when attempting to foster cognitive aspects of creativity.

Certain process strategies are very useful when looking for original ideas. As a result, creative process strategies for enhancing creativity are quite numerous and include teaching people to use cognitive tactics such as lateral thinking, brainstorming, SCAMPER (substitute, combine, adapt, magnify/modify/minify, put to other uses, eliminate, reuse), analogical reasoning (e.g., synetics), and creative problem solving. Other frequently mentioned strategies include identifying and overcoming blocks to creativity, balancing the use of reflection and tinkering, encouraging playfulness, creativity imagery or visualization, utilizing multiple perspectives, questioning assumptions, and looking for patterns. Perhaps the most popular techniques of the past 50 years have involved the teaching of divergent thinking and general problem-solving tactics and heuristics.

The role of information stores has received considerably less attention during discussions of creativity than that of cognitive processes, but the role may be no less important. Expert problem solvers tend to have better working and long-term memory skills than novices, although this distinction only applies to the memorization of situated knowledge (i.e., information that can be placed into an expert's existing schema) and not tangential or random knowledge. In addition, general knowledge may be very important during the creative process, and such knowledge depends on memory and information storage. Without well-organized information stores (i.e., schemes), knowledge becomes difficult to use and recall during the creative process. Constructivist approaches to learning, in which individuals construct their own schemas based on their personal experiences, should prove especially useful when helping people learn to retain, recall, and apply knowledge during the creative process. Jean Piaget, the well-known psychologist, titled one of his monographs, *To Understand is to Invent*, implying that true understanding depends on personal constructions of knowledge. Very often it is beneficial for students to relate new information to prior knowledge (i.e., existing schema), and activities should be based on realistic problems that require application of prior knowledge and new skills. Much new work on divergent thinking and creative problem solving relies on realistic problems.

The importance of prior knowledge can, however, be easily overstated or mislead. That is because an individual or group that is immersed in a particular field of study or interest area may be reluctant to consider ideas and solutions that are uncommon, unpopular, or even antiparadigmatic within that context (or within one's personal experiences). This phenomenon is referred to as functional fixedness or rigidity. It has also been called "the cost of expertise." Whatever the label, the result is that creative contributions in a given area are often made by individuals who are not necessarily experts within that field. A case in point is the numerous early paleontologists who had primary training in the arts. When painting and drawing illustrations of dinosaurs, they realized that the existing knowledge base was quite superficial and provided inadequate answers to many important questions. Their fresh perspective allowed them to move beyond existing paradigms and field-based constraints to make creative contributions to paleontology. Other examples include experts who retain flexible strategies while maintaining their expertise in certain domains.

Although many people believe that the exponentially increasing complexity of most disciplines has led to creative contributions to these fields, it is probably an overstated belief. The ability to apply processes and use information from areas of interest other than one's own area of interest is clearly important. The tension between different areas of interest may stimulate creativity as well. When

participating in creativity enhancement exercises, people should thus be encouraged to look across fields of study and areas of knowledge for potential solutions to their problems. This act of looking beyond the established parameters to obtain a solution to a problem has popularly become known in business circles as thinking outside of the box and psychology as insight, moving beyond the problem space, or problem finding and redefinition. Other specific strategies in this area include forcing someone to assume a different viewpoint or perspective on an issue, which can be facilitated by a debate or role playing.

Experts tend to exhibit a greater degree of meta-cognition during problem solving than do novices. In this context, metacognition involves monitoring one's own cognitive processes in order to manage time effectively, assess progress accurately, and attempt problem-solving efforts efficiently. Suggested strategies for helping students develop metacognitive abilities, which tend to develop in preadolescence, include providing a variety of creative and problem-solving strategies in a low-risk, constructive environment, encouraging self-assessment of the steps taken to solve a problem, and modeling metacognitive skills. Metacognition and its benefits are not to be expected of young children.

An intriguing, recent development is the use of transcranial electrical stimulation (tES) to stimulate specific regions of the brain to enhance cognitive aspects of creativity. The research on tES is in its early stages, and questions about long-term efficacy and results of repeated use have yet to be addressed. In addition, such manipulations raise a host of medical, ethical, and social issues that are just beginning to be debated. But the initial, positive outcomes of tES research are certainly a harbinger of future enhancement efforts as our understanding of human neurology and its potential manipulation continue to expand.

Affective Components

The affective component of creativity refers to one's emotions. Affect is quite important because creative work very likely has personal meaning to the creator. In addition to fostering creativity through the creator's personal engagement with the world, efforts at understanding those creative outputs and enhancing their expression should consider creativity's vibrancy. Bleakley (2007) identified ten different aspects of creativity: progress, conservation, innovation, transgression, discipline, complexity, inspiration, serendipity, negative capability, and withdrawal. Enhancing creativity requires consideration of its multifaceted nature and offering modifications as necessary, based on the individual, the environment, and the purpose.

Furthermore, a technique used to enhance creativity should provide more than just a new strategy – it should provide a practical use for the strategy. Benefits to individuals or society should be communicated, and intrapersonal and interpersonal incentives described. Without the aid of extrinsic motivation, the creator may become unmotivated.

Care must be taken, because – in contrast to the potential of incentives – the positive relationship between intrinsic motivation and creative behavior is well documented in the theoretical and empirical literature. But the question of whether external motivation (especially when created by external evaluations) is detrimental to creativity has yet to be fully answered. E. Paul Torrance suggested that freedom from evaluation during practice with a creative strategy resulted in more proficient use of that strategy over time, but he found this to be less true with older, late elementary students than with younger students. Other researchers have called into question whether extrinsic motivation is truly detrimental to creativity, with a few theorists going so far as to say that constrain and external motivations are essential for creativity to emerge. Very likely both are potential influences, with the contribution of each varying across individuals and tasks.

Additionally, cross-cultural application of creativity evaluation must come with a caution. It is easy to fall prey to different cultures' perceived ability (or inability) to foster and appreciate creativity based on social norms and values. Substantial work has done on creativity enhancement in East Asian countries compared to Western countries, but appropriate consideration of both the theoretical generalizations and the local variations is necessary in understanding how to apply findings from other contexts. These findings can become cultural stereotypes with little explanatory or educational value.

Given the controversy surrounding external motivation, recommendations regarding evaluation and creativity should be made judiciously. One's creativity should be subject to reasonable amounts of evaluation, but only when the evaluators are trained in how to provide constructive criticism – and the creator is willing and able to receive that feedback and use it to improve their creative work.

Attitudinal Components

Over the past 20 years, researchers and theorists have increasingly appreciated and emphasized the role of attitude and motivation in creative achievement. One's belief in his or her ability to create, defined broadly, forms an important part of the psychological foundation of creative achievement. Creative self-efficacy can be fostered by providing genuine praise and feedback about a person's creativity and avoiding discouraging statements (e.g., "You can't do that, you're not creative"). But some people may be challenged by competitive statements, again stressing the value of constructing enhancement efforts on a case-by-case basis.

Although an individual's attitude can influence whether creative problem-solving skills are applied, it is important to consider if the individual has the ability to tap into these techniques. Basadur's enhancement work posits that a lack of knowledge about how to apply creative principles may hinder their application. Creativity training can be an effective solution, but it should also foster positive attitudes about creative approaches. Basadur advises that programs designed to encourage creative problem-solving may

not have the desired effects if individuals' attitudes about creativity do not become or do not remain positive. Programs which are designed to foster enhance applications of creativity should consider how attitudinal factors will be addressed (See Motivation).

The attitudinal enhancement of creativity may involve modeling, which can be accomplished in a variety of ways. Individuals can be exposed to information about unambiguously creative individuals, perhaps via biographies or case studies. These can provide a glimpse into the more personal aspects of creativity and provide evidence that even eminent creators "are just human, like you and me." This kind of information can be reassuring and even inspiring, though it does not suggest specific ways to be creative. It is informational in the literal sense, providing factual rather than procedural information about creativity. In a similar vein, teachers, managers, parents, and others who are attempting to foster creative self-efficacy in others should model a can-do, enthusiastic attitude when confronted with problems and tasks that require creative solutions. By explaining their thought process as they tackle the problem, the creative process may be further demystified and made more accessible to the observer.

In order to change perceptions, six myths of creativity have been identified. They are as follows:

- Myth 1: People Are Born Either Creative or Not Creative. As previously discussed, research suggests that individuals may enhance their own creativity, but this often times is not believed by the individual.
- Myth 2: There Is Limited Time to Be Creative (Aging diminishes creativity.) An oft held conception of creativity is that it is an ability that most children tend to possess. Much research suggests that older adults actually demonstrate the ability to be creative.
- Myth 3: General Creativity Does Not Exist. While there are data suggesting creativity is specific to an area, recent theory and supporting data suggest that some types of creative methods move across domains while others may be more limited within domains.
- Myth 4: Creativity Is a Touchy-Feely Phenomenon. Many seem to believe that creativity is this magical and mystical ability; only attained when one is not really trying to find it. Creativity can and has been studied using rigorous methods with well-conceptualized operational definitions.
- Myth 5: Group Creativity Works Best. Both group and individual creative strategies have advantages and disadvantages. These differing values are described in the next section of the article.
- Myth 6: Constraints Hinder Creativity. Although constraints may sometimes hinder creativity, they may also help provide positive guidelines that promote creativity.

These myths also represent a useful part of the framework for creativity enhancement programming via attitudinal change to be discussed later in the article.

Interpersonal Components

Several kinds of interpersonal interactions appear to facilitate the creative process. Two important skills are the ability to gain acceptance for one's creativity and the ability to work with others during the creative process. Although there is considerable debate about whether gaining acceptance for creativity (i.e., persuasion) is a vital component of everyday or only eminent creativity, the ability to market personal or group creative products can be a positive attribute [Plucker \(2016\)](#). Students should be encouraged to share their creative work with others. It is hoped that they will receive and benefit from this positive and perhaps even mild negative feedback. This may help them to develop the ability to convince an audience of their creativity. Other important interpersonal influences were suggested by Carl Roger's Humanistic theory and have empirical support. These involve the support of psychological freedom and psychological safety. According to Rogers (and the data supporting his ideas), these lead to the three internal conditions for creativity, namely openness to experience, the ability to toy with concepts, and an internal locus of the valuation (See Self-Actualization).

Working with others can both foster and inhibit creativity. Groups can serve as a detriment to creativity when members are simply told to 'do well,' when group goals are lacking, and especially when members do not have the freedom to work as individuals within the larger group. Conversely, groups tend to enhance creativity when members are socially comfortable with each other, when both the group and the individual members are held accountable for clear performance standards, and when group tasks are meaningful. Recall also the potential impact of evaluation, which can also be interpersonal. Efforts to enhance creativity via groups should keep in mind that collaboration and physically working in a group are not necessarily the same thing.

A seldom mentioned aspect of group creativity is the intergroup interaction as each group solves similar problems. By allowing group members to interact with other groups, the informal sharing of information and ideas can help members of a group overcome any functional fixedness that has developed. This perspective, which is based on the work of social constructivists, suggests that intergroup communication should be encouraged (See Group Creativity).

Problem-based and situated learning is also relevant to the discussion of interpersonal components of creativity. These constructivist-inspired strategies, which allow students to learn content and process skills through the solving of real-life problems, place a strong emphasis on the application of information rather than on simple memorization. Additionally, the realistic nature of problem-based and situated enhancement efforts fosters intrinsic motivation, which can be beneficial for creativity. Although situated learning makes sense in light of constructivist learning theories, situated approaches pose certain problems for the enhancement of creativity. Constructing knowledge and developing creative process skills may be more applied in a situated context, but they may be constructed and developed in a way that promotes functional fixedness. Problem-based learning activities should be designed so that students are required to apply factual and procedural knowledge in a variety of contexts, to interact with others as

part of the learning process, and to engage in some abstract thought (i.e., non-situated thought, which is frequently mentioned as a cognitive characteristic of creative individuals).

Environmental Components

The assembled research from the past 50 years paints a clear picture of the characteristics of a creativity-enhancing environment. The key characteristics are tolerance, moderation, and availability of resources. Thus, a stimulating environment should be created with a multitude of diverse materials (i.e., resources) available to stimulate ideas and create solutions. The not uncommon tendency to provide predominantly verbal materials should be avoided. Many individuals prefer to express their creativity through several domains, thus varied input (e.g., visual) should reflect this diversity of expression. In addition, given the importance of problem finding, it may be desirable to expose people occasionally to open stimulus environments, in which stimuli must be sought and problems need to be identified.

The environment should allow and even encourage reasonable risks to be taken, but irresponsible and physically dangerous risks (e.g., consumptions of drugs) should be discouraged. Everyday uses of creativity and problem solving are fostered by the management of risk, not simply by taking any risk that presents itself. In more general terms, the creative environment fosters the use of creative discretion, which separates originality from psychotic ideation.

Deviance and ambiguity are tolerated in the creativity-enhancing environment. Individuals should be encouraged when they think outside of accepted procedures and customs, and not criticized for ignoring cultural and experiential limitations. However, the environment should encourage self-regulation of creative processes so that even the most exhilarating dead ends can be self-identified and put aside. Divergent thinking needs to be linked with convergent thinking in the creative environment.

In general, the environment should be marked by balance: a mixture of structured and unstructured tasks that require divergent and convergent thinking, independent and group work, and procedural and declarative (factual) information.

Drug Use

Conventional wisdom posits that the use of certain drugs (e.g., alcohol, marijuana, LSD) can sometimes enhance personal creativity. Although certain aspects of creativity (e.g., affective, cognitive, interpersonal) may be positively influenced by drug use, research over several decades provides convincing evidence that – at best – moderate drug use has a negligible effect on long-term creative production and heavy use has a detrimental effect. Even in specific situations where a positive drug effect has been documented, the drug does not appear to encourage creative production. For example, several researchers have observed that alcohol consumption tends to lower a person's inhibitions, which is assumed to result in more flexible thinking and, therefore, greater creativity. However, this research has also shown that the disinhibition does not lead to enhanced creative production, rendering the effect of the alcohol most with respect to long-term creative productivity. Possible exceptions to these findings may be the use of caffeine and psilocybin, which may be correlated with creativity but are currently understudied in this regard (See Drugs).

Programs Designed to Enhance Creativity

Over the past few decades, several creativity training programs have been used to help people maximize their creative potential. These programs usually incorporate strategies that address multiple components of creativity.

Two types of programs have been designed to enhance children's creativity. The first involves modifications of the regular school curriculum, such as the Schoolwide Enrichment Model and Mentor Connection, the Talents Unlimited Model, the Cognitive–Affective Interaction Model, the SOI system, and the Purdue Creativity and Enrichment Models. The second includes extracurricular programs that may or may not be affiliated by educators attached to a child's school, including the Odyssey of the Mind and Future Problem Solving programs and numerous local, regional, and national invention programs. However, the distinction between these two types of programs is not universal, and programs frequently and successfully transverse this rather artificial boundary.

Within the business community, programs for enhancing creativity are quite popular. The increasing popularity of creativity in the business sector has led to an explosion in the number and type of programs aimed at this audience. In general, the components mentioned previously in this article are included in these programs, with predictable changes in terminology.

Plucker and his colleagues developed and evaluated a new approach to enhancement, one that focuses on attitude change as the precursor to enhancement. The model for the curriculum includes (a) changing schemas, (b) identification of personal strengths, and (c) acknowledging personal and external factors that may affect creativity, all addressed through a series of problem-based activities. The developers created two courses: an entry level course titled *Debunking Myths and Enhancing Innovation*, and an *Applied Creativity Seminar*, a capstone class for undergraduates. Pre- and post-course data suggest that students are able to overcome initial misconceptions and begin to change attitudes about creativity. This was particularly strong for the beliefs that creativity can be enhanced, that creativity can be defined, and constraints may enhance creativity. Although further testing of this model is needed

within the framework of the courses or similar courses at other universities, initial evidence suggests that focusing on attitude change rather than specific cognitive skills or behaviors may be a fruitful approach for enhancement programs.

Creativity Research in the Workplace

The application of creativity research extends beyond education into the workplace. Employers desire creative professionals to increase market competitiveness. In other words, they wish to enhance worker creativity to achieve corporate success. The research on creativity in workplace environments probes the dynamic relationships between the environment and the employee. It also attempts to differentiate workers' deliberate creative applications from their unexpected creative products, but these attempts are not always successful. Moreover, it is important to note the attempts to combine workplace definitions of creativity and innovation to reveal confusing patterns. Further research is needed to examine the relationships among the environment, the worker, creativity, and innovation. As creativity research advances, the intricacies of these relationships can become clearer.

Conclusions

Must all of the components be present in an effort to enhance creativity? As mentioned earlier, aspects of each component have been studied individually. Similarly, intervention efforts occasionally focus on only one or two components.

However, because each of the components is a necessary but not sufficient condition for creativity, enhancement efforts that consider the components collectively should be more effective than narrowly focused strategies. For example, if a person was to choose one component to exclude from enhancement efforts, which would it be: creating a supportive environment in which people are encouraged to take sensible risks, encouraging people to monitor their creative processes, or stressing the importance of interpersonal skills to creativity and the creative acceptance process? Each is clearly important and overlooking any of them (or any other aspect of creativity) would be difficult in light of the assembled research and theory. Although efforts to foster creativity need not focus on each and every component (and cannot do so effectively), well-designed programs consider all of the components and their interactions.

With the ideal that all facets of creativity should be represented in enhancement efforts, the following general guidelines appear to be reasonable.

1. Consider addressing misconceptions people have about creativity. For example, if a student does not believe he or she is creative and believes creativity cannot be increased, the best instruction for creativity enhancement will probably have little impact on that student's creativity.
2. Design activities that demand an individual's or group's attention. Capitalize on teachable moments such as current political, cultural, and community events. Try to address personally meaningful, intrinsically motivating topics.
3. Supply information about strategies and creators that is both useful and interesting. Information on the difficulties in building a canal or on intricacies of Einstein's general theory of relativity may not appeal to a group of marketing specialists, but stories about Einstein's struggle to get his ideas accepted or about the political creativity involved with constructing sky-scrapers may appeal to this group.
4. Provide either the skills and information that will generalize to other settings (e.g., the home, school, workplace) or opportunities to apply the introduced skills and information to different settings and problems.
5. Encourage people to share their creative work and learn how to incorporate feedback into their creative processes. Conversely, work with groups to learn how to provide constructive criticism that can improve and enhance the creativity of others.
6. Remove excessive evaluation and supervision from the creative environment. Micromanaging is just as disruptive to young students as it is to corporate managers.
7. Attempt to alter attitudes about creativity and originality and encourage creative confidence (i.e., creative self-efficacy) and risk taking.
8. Design activities that excite, stimulate, and increase curiosity and help people develop the intrinsic motivation to be creative.
9. Require problems to be solved individually and in groups. Have groups critically examine their own processes and attitudes (i.e., develop group metacognition) during and after the creative process.
10. Avoid making assumptions about students. Recent theory and research on intelligence, motivation, personality, and mindset provide evidence that individuals vary tremendously in their abilities, preferences, and attitudes. This diversity appears to be a critical element of creative production.
11. Similarly, introduce variety into enhancement efforts. This capitalizes on individual preferences and interests and promotes diversity in one's approach to finding and solving problems.
12. Consider the use of well-established programs that address multiple components of creativity and have already been field-tested and refined.

Introduction

The Center for American Entrepreneurship defined entrepreneurship as “the process by which individuals or a group of individuals (entrepreneurs) exploit a commercial opportunity either by bringing a new product or process to the market or by substantially improving an existing good, service, or method of production. This process is generally organized through a new organization (a start-up company) but may also occur in an established small business that undergoes a significant change in product or strategy (see below on growth).” Parthasarathy, Daboli, and Paulus explained the relation between entrepreneurship and creativity as follows: to initiate a new business, entrepreneurs need a novel, financially sound, and technologically feasible idea that satisfies the need of a specific, large enough market. Accordingly, a business idea is the most crucial part of an entrepreneurial cycle and determines entrepreneurial success. Entrepreneurs need to be creative in order to identify new business opportunities so entrepreneurship and creativity have a natural affinity. This article considers this notion, drawing heavily on Parthasarathy’s research.

Entrepreneurship and Entrepreneur Definition

An entrepreneur is “a person who organizes the means of production to engage in entrepreneurship often under considerable uncertainty and financial risk. Entrepreneurs may partner with other entrepreneurs to jointly found companies (co-founders) or with an existing organization (e.g., corporate or university spin-outs).” In other words, entrepreneurship is the process of creating new businesses to deliver novel products, services, or a marketing state of mind. Entrepreneurship implies exceptionally optimizing the resources of production to innovate, improve customers’ lives, create wealth for enterprises, and add value to society. Entrepreneurs possess the required skills and initiative to bring novel ideas to the market. There is a continuous and conscious effort required to look for niches and undertake the risks in entering them. Entrepreneurs who prove to be successful in taking on the risks of a startup

are rewarded with profits and continued growth opportunities. Those who fail suffer losses and become less prevalent in the markets.

The Entrepreneurial Process and Embedded Characteristics

Entrepreneurial development begins with the conception and refinement of business ideas, followed by implementation and management. The process of creating prospective business includes the following six phases: (1) opportunity recognition, (2) idea incubation, (3) business preparation, (4) feasibility analysis, (5) implementation verification, and (6) management dynamics. This process is parallel to the traditional creativity process (i.e., problem finding, idea generation, and idea evaluation).

Phase 1: Opportunity Recognition

This is a key element of the new venture's creation process. Capable entrepreneurs identify gaps between demand and supply. These gaps may exist when certain things need improvement as well as when specific preferences or ambiguous requirements need to be satisfied. The identification of these gaps is a cognitive process that demands unusual perspectives. Accordingly, entrepreneurs evaluate opportunities to meet the market needs by introducing a product or service to improve, satisfy, please, or close the market gap. An entrepreneur's motivation, passion, and ability to recognize business opportunities determine business success. Thus, identifying market gaps, transforming them into opportunities, and generating business ideas to fulfill market needs are essential aspects of this phase.

Phase 2: Idea Incubation

Seizing evanescent business opportunities requires the formulation of novel and unique business ideas. These ideas must be incubated through candid self-examination to identify entrepreneurial skills and then implemented with market research to identify customers' requirements. During the incubation phase, ideas that have the potential to solve problems are generated. This phase is characterized by the conscious or unconscious thought process for refining an idea. Incubation leads to the clarity of ideas. This creativity process is referred to as re-creativity, as it takes inspiration from existing ideas and molds them in an innovative way. Accordingly, a self-disciplined process of evaluating and refining business ideas must be executed throughout the entire entrepreneurial process.

Phase 3: Business Preparation

This stage involves the preparation of some practicable ideas. There has to be some inspiration that forces or prepares entrepreneurs to move forward. This is a critical stage for entrepreneurs to stay motivated and launch their ideas in the form of a business plan; they must also consider the availability of resources required. An entrepreneur identifies the target market and makes adjustments to suit market needs for a start-up or expansion. This is done in an effort to identify a viable solution. Through business preparation, entrepreneurs zoom in and out to examine all possible directions to solve the problem, be it inside the industry or outside. In short, transforming thoughts into actions and flexible adjustment to suit market requirements are essential for business preparation.

Phase 4: Feasibility Analysis

In this phase, entrepreneurs decide to seek, obtain, and use resources. Entrepreneurs have identified the market gap and opportunities and outlined a business plan after considering the financial implications for start-up. A series of light tests, corrections, and retests are conducted to prepare a business plan poised for growth. If potential customers perceive value in the offering and are willing to pay for it, this implies the pressing need from the target market and validates the business idea. At this point, entrepreneurs would focus on acquiring financial backing for their business ideas. Obtaining funding is one of the major obstacles to start a new business. Entrepreneurs invest resources to ensure a positive first impression on their customers. Considering financial burdens, getting potential customers to bank on the business practices is a major breakthrough.

Phase 5: Implementation Verification

This stage determines whether the new found business practice has the potential to work or not. No business can stay afloat without customers. Entrepreneurs aim to acquire as many customers as possible at a reasonable cost as well as to retain them in the most effective way. Accordingly, entrepreneurs are required to consider customer acquisition and retention costs while operating their businesses. Offering exceptional customer services may attract customers and win their trust. Happy customer testimonials build a sense of trust in people who have not patronized their business before. Therefore, honest opinions about the business practice must be provided by entrepreneurs. In short, the business practice can be either accepted, modified with changes, or rejected altogether to safeguard its implementation.

Figure 1 Entrepreneurial process.

Phase 6: Management Dynamics

The major success of any entrepreneurial effort depends on critically examining the feasibility of an idea. After operating for a few months, entrepreneurs could see if their start-ups show increased, constant, or decreased sales. Although every entrepreneur strives for victory, any entrepreneurial process could result in success or failure. If the business model used does not work, entrepreneurs could revisit the events that led to its failure. Highlighting their areas for improvement, entrepreneurs could accumulate experiences over time that would help them handle most problems. As the business develops, customer satisfaction and revenue growth are critical. In short, creating and managing a business are difficult; the viability of business practices can lead to the creation of actual enterprises or the improvement of existing ones.

The entrepreneurial process is bounded by context rather than a step-by-step approach. As illustrated in Fig. 1, this process comprises six phases without strict boundaries. The entrepreneur starts with opportunity recognition and then moves through the phases of idea incubation, business preparation, feasibility analysis, and implementation verification. The invention of business ideas and the refinement of associated practices in each phase influence those in the next phase, eventually leading to the management of market dynamics.

Significance of Creativity in Entrepreneurship: Four Challenges

Entrepreneurship is a multifaceted and somewhat risky career path. Qualities such as intelligence, passion, and determination can help entrepreneurs achieve success. Nevertheless, creativity should be valued above all others because entrepreneurs are required to produce innovative ideas and ensure business success. Creativity is not only the accelerator of entrepreneurial development but also a stronger predictor of business success than intelligence. Creativity is a characteristic that distinguishes them from traditional businessmen.

Entrepreneurs face the following challenges:

Opportunities Should Not Be Overestimated

A start-up typically begins with a small business having immense flexibility. Identifying opportunities and visualizing ways to activate them particularly need creativity and are crucial for small business entrepreneurs. However, many entrepreneurs are keen on seizing opportunities or are over-optimists to diversify their business operation. Numerous successful entrepreneurs do not launch a radically new product so much as a significantly improved one. Entrepreneurship increases an enterprise's wealth and adds value by rising economic activities resulting from optimizing the entire process. Changing the manufacturing method for the products or shifting ways of supplying products and delivering services to customers can create a niche with great business potential.

Accordingly, a careful market opportunity analysis should be conducted for identifying customer problems and satisfying unmet customer requirements. The following steps assess the attractiveness of a new market opportunity: (1) understanding the current business environment, (2) identifying potential markets, (3) defining profitable targets, (4) diving into the details of competitors, (5) offering an attractive prospect to the target market, and (6) setting and testing sales projections. Creative insights are required in-between these steps for integrating customer information, available resources, and competitive readiness in a meaningful manner, ensuring that opportunities are not overestimated.

A Business Idea Must Have Potential Economic Value

Divergent and convergent modes of thought must be combined for entrepreneurs to have creative breakthroughs. A divergent approach generates creative ideas by exploring possible solutions to the same problem at the intersection of disciplines. Most breakthrough discoveries, including exceptional business ideas, occur when two or more disciplines collide, allowing entrepreneurs to view a problem and decipher potential solutions from a new perspective. A convergent approach is highly analytical and focuses on arriving at one accurate solution given the available data and resources, frequently working with computer systems and accounting software.

Creativity requires structure for successful execution, but the structure should not be too rigid. Business ideas cannot be exceptional unless their economic importance is highlighted. In other words, creative business ideas work best when harnessed with

highly focused and disciplined thought. Exceptional business ideas result from following a divergent approach at the preliminary stage and convergent approach at the execution stage, giving entrepreneurs an edge over the competition.

Nonstop Innovation Is Vital

Creativity extends the limits of entrepreneurs' mindsets and skill sets. It enables people to connect dissimilar and unrelated subjects and generate successful entrepreneurial ideas. Although some innovations are incremental in nature, interdisciplinary collisions are essential for transcending the boundaries established by different professions. As such, feasible resolutions from unrelated concepts can be explored before potential path-breaking discoveries. Capable entrepreneurs repeatedly seek innovation to thrive for success. Their current idea is often only a transition into another idea because situations constantly change in a start-up.

Adapting to circumstances and putting continuous efforts to generate new ideas are a part of entrepreneurship. Entrepreneurs' market success represents that competing products or services, better than theirs, will be promptly developed and delivered. Accordingly, entrepreneurs must ensure conscious efforts to innovate their products or services and continuously search for niche markets. Therefore, capable entrepreneurs think in original ways to generate interesting, versatile, unthinkable products or services and yet have the potential for success.

Entrepreneurs Must Be Risk-Takers

Entrepreneurs are required to undertake risks to redesign their products or services to stay ahead of their competitors as well as to relocate their existing business workflows for effective implementation. They are required to leave their comfort zones and consider conflicting opinions. Creativity allows entrepreneurs to disconnect from the accustomed and move into uncharted terrains to discern unique and useful solutions. Patience is required to observe the fruitful outcome of business ideas and practices. It takes time and effort to transition from conceptualization of ideas to their implementation.

A start-up typically has limited funding and faces a constant struggle to maintain positive cash flow, requiring entrepreneurs to exploit their creative resources. The entrepreneurial process rewards entrepreneurs by increasing their profit potential. However, entrepreneurs must step in and resolve problems themselves. The ability to foresee situations in detail, identify the choices, and visualize the best decision demands creativity. There is always room for improvement in the deliverables of an enterprise; capable entrepreneurs have the skills and vision to assess how to do it. If they do not optimize their businesses, they will promptly lose market share to newcomers.

Entrepreneurial Creativity and Entrepreneurial Intentions

Researchers have extensively reviewed entrepreneurial creativity and entrepreneurial intentions. Entrepreneurial creativity is defined as the business capacity to discover and exploit business opportunities for generating and implementing creative ideas, thereby establishing new ventures or reviving existing organizations. Entrepreneurial creativity can be assessed in terms of originality and usefulness. Entrepreneurial originality refers to the capability to generate business thoughts and practices considered to be novel or unique within the marketplace. Entrepreneurial usefulness refers to the capability to generate business thoughts and practices considered to be appropriate, effective, or valuable within the marketplace.

Extrinsic and intrinsic factors influence entrepreneurial activity. Among the extrinsic forces, the role of cultural background should be emphasized. The behavior of individuals largely reflects their cultural background. Cultural background offers a range of social stereotypes and rules that form an individual's frame of mind that contributes to their understanding of the world. Specific cultural characteristics, such as allowing new ways to work and live, encouraging individual achievements and perspectives, and having high rates of innovative activity, are labeled cultural creativity.

The second force is institutional environment, which is influenced by cultural background and political operation to create structures and incentives for individual and group actions. The structures and incentives are formed as economic stability, capital availability, personnel regulation, legal protection, and the degree of power centralization. In addition, the management of resource availability is a critical force to boost creativity, particularly when creative capital must be funded. Technological advancement, another frequently mentioned extrinsic force, leads to a sharp change in performance to drive discontinuous capability improvements and product developments. This would create new business opportunities and investment options and result in new potential market and customers.

Personality traits should be highlighted as an intrinsic force that enhances creativity. Over the years, numerous researchers revealed five traits of creative individuals: high openness, low agreeableness, low conscientiousness, high extraversion, and low emotional stability. Furthermore, entrepreneurial creativity demands motivational synergy resulting from a combination of intrinsic motivation (i.e., strong levels of personal interest and active involvement) and certain types of extrinsic motivation (i.e., supportive incentives) to empower further achievement. Moreover, emotions can negatively impact human reasoning and creative thinking. Numerous studies have further indicated that self-efficacy influences workplace creativity, a key driver of organizational innovation and success.

Research studies also suggested that social support leads to ideational productivity and creative performance. In addition, prior experience has been identified as a crucial predictor of creative performance because it may help people avoid unnecessary try-outs

and lead them to possible resolutions. However, some studies suggested that prior experience may not always be beneficial to market alertness and business creation. Furthermore, the greater the knowledge base of individuals, the more the ideas and the combinations that they can achieve. Accurate knowledge management metrics allow an organization to become more creative and sustainable, thereby achieving a competitive advantage. High levels of creativity are associated with a high level of education, which encourages individuals to think in a certain way by equipping them with the necessary tools to develop innovative practices in the future.

Entrepreneurial intention is defined as a person's self-acknowledged conviction to establish a new business venture and the conscious planning to do so in the future. Research indicated that entrepreneurial intention is a strong predictor of planned behavior and functions as a mediator or catalyst for entrepreneurial action. Entrepreneurial intention comprises two factors: conviction and preparation. Entrepreneurial conviction refers to a strong belief or opinion toward entrepreneurial career commitment. Entrepreneurial preparation refers to the activities or processes that prepare a person for being an entrepreneur.

Accordingly, cultural background, institutional environment, resource management, technological advancement, personality traits, motivation, emotions, self-efficacy, social support, prior experience, knowledge base, and educational levels play critical roles in facilitating entrepreneurial intention. In addition, previous studies tested and validated that entrepreneurial creativity can serve as a robust mediator between the aforementioned factors and entrepreneurial intention.

Entrepreneurial conviction is influenced by both dimensions of entrepreneurial creativity, whereas entrepreneurial preparation is strongly influenced by entrepreneurial originality. Thus, educators should inspire students to implement their unique ideas and encourage them to generate novel works, thereby facilitating entrepreneurship preparation. Educators can lead students to construct effective ideas and assist them in generating valuable works, thereby further promoting entrepreneurship conviction. In addition, educators should provide positive experiences for students to engage in entrepreneurial activities and embed career flexibility into their coursework design and placement experience planning.

Ways to Boost Entrepreneurial Creativity

Everyone is born with creative potential. Creativity is a renewable resource that can be tapped into at any time, and the creative process can be improved and reinforced. Inculcating new hobbies can be an ideal way to put individual creativity to test and hone creativity. Entrepreneurs cannot always depend on aha moments for professional achievements. Intrinsic factors such as motivation, emotions, self-efficacy, perceived social support, prior experience, and knowledge base can be altered to boost entrepreneurial creativity.

Take Mental Breaks

The best way to refresh the brain is to step away from the workplace and take breaks for pushing oneself over the last mental hump before all good ideas are squashed. Relaxing on a comfortable sofa, reading an article, listening to music, or drinking a cup of coffee or beer can reboot creativity and lead to the generation of ideas. Dimming the surrounding lighting to reset emotion and letting the mind drift can actually advance creativity, lower inhibitions, and even raise one's determination. A calm and uncluttered mind is beneficial to entrepreneurs for enabling their creativity to flow. Neuroscientists confirmed that exercise can accelerate the birth and survival rate of new brain cells of the hippocampus, a region responsible for human memory and for the ability to imagine the future and to think creatively. Going for a run can sharpen peoples' minds, help them to stay focused, and allow them to detach from their subject experiences to observe their own thoughts. In short, beyond mental dexterity, creativity thrives when there is emotional balance and mind relaxation.

Change Comfort Zones

Comfort means to set boundaries around one's accustomed frames and a state of physical ease. However, with high levels of motivation and self-efficacy, capable entrepreneurs change comfort zones to contribute to business success. Sometimes, revisiting and visualizing things from a different perspective can help entrepreneurs separate themselves from stressful situations. Entrepreneurs may devise new ways of doing the same task. Working backward may provide entrepreneurs with smarter solution and keep their creative spark bright. In brief, possessing multiple comfort zones that can be freely moved in and out of helps entrepreneurs to identify viable ideas for business growth.

Encourage Knowledge Sharing and Welcome Constructive Criticism

By exploring different roles, entrepreneurs can adapt to changing and make accurate decisions. Successful entrepreneurship requires sufficient viable ideas. Creative thinkers need to think of all possible alternatives, which help in compiling diverse ideas. Through sharing ideas, taking criticism, and soliciting feedback, multidimensional perspectives may be drawn. In short, a team of creative thinkers can be the greatest asset for every entrepreneur, and every creative mind increasing an enterprise's value should be well rewarded.

Evaluate Business Ideas and Practices Against Goals

Capable entrepreneurs complete short-term tasks while keeping long-term goals in mind. These goals should be displayed, so that entrepreneurs can work to achieve them every day, in addition to keeping weekly plans. In the start-up process, entrepreneurs never consider a static plan; instead, they keep evolving the plan because it always can be inspired from emerging thoughts by transforming and combining them.

Free thinking is a primary business practice nowadays; it must revolve around a specific goal with some parameters. Some checkpoints offered by Princeton Creative Research are as follows: thinking based on realistic needs, pinpointing issues for resolution, having expected outcomes of implementation, knowing limitations and risks involved, demanding simplicity in implementation, grasping needs of potential customers, and accompanying marketing strategies. In short, devising easier plans and evaluating business ideas and practices against goals can help facilitate successful entrepreneurship.

Social Entrepreneurship

Definition and Importance

The social entrepreneurship movement is gaining momentum worldwide, and business school leaders have identified it as one of the most in-demand areas of business research. Social enterprises are organizations that combine social missions with financial autonomy in a competitive corporate environment. Social enterprises improve social welfare through the commercialization of goods or services. These organizations are innovative agents that engage the market and harness its wealth-generating power for serving disadvantaged social groups and achieving social transformation. They use commercial operations to promote their claims of social, environmental, and practical justice. In short, social entrepreneurship aims to resolve social problems through social entrepreneurs who establish liaisons between social causes and entrepreneurial actions in organizations.

Three major schools of thought exist regarding the concept of social enterprise: “earned income,” “social innovation,” and the “EMES (EMERGENCE des Entreprises Sociales en Europe [the European Social Enterprise Research Network]) approach.” The earned income approach refers to the use of commercial activities in support of a nonprofit organization’s (NPO’s) social mission; social innovation approach refers to playing the role of a change agent by pursuing new opportunities to serve a mission to create and sustain social value. The EMES approach refers to those financially autonomous NPOs providing goods or services related to their aim to benefit the community. This article considers a social enterprise as the use of commercial methods for social innovation and financial sustainability in support of an organization’s creation of social values.

The importance of social enterprises has been affirmed twice by the Nobel Prize. For the first time, in 2006, the economist Yunus was awarded the Nobel Peace Prize for creating the Grameen Bank in Bangladesh, which grants loans to poor people through innovative operations to improve their lives. The Grameen Bank has advanced to the forefront of a burgeoning world movement toward eradicating poverty. The Grameen Bank model has been duplicated in over 100 countries worldwide.

The second affirmation was in 2009, when the Nobel Prize went to American political economist Elinor Ostrom who examined ways communities cooperate with each other and conduct joint resource governance. Ostrom demonstrated that local property can be effectively managed by local communities without any regulation by central authorities or privatization. This insight helped people appreciate human behavior by advocate for communities that self-organize in ways that punish those who take undue advantage of common resources.

Social enterprises are increasingly compelled to engage in the market economy, and they share characteristics with earned income ventures initiated by conventional nonprofits because both are driven by the dual goals of social benefit and trade revenues. In addition, social enterprises have used their community-spirited motives to attract human and social capital and engendered survival strategies premised on grant dependency. Because of its dual-targeted characteristics, social entrepreneurship often creates nonprofit sector jobs, fosters workforce development, and provides people with supplemental income, often by strengthening ties between entrepreneurs and the formal economy and building social capital.

Performance of Social Enterprises

With the increasing use of managerial practices, optimization has become crucial for organizational performance. The issue of performance measurement in social enterprises has gained increasing relevance among researchers and practitioners. Previous studies indicated that performance measurement for social enterprises must include both organizational performance and social impact. Studies also suggested that entrepreneurs, management teams, and service programs play critical roles in the performance of social enterprises. Next, the performance measurement of social enterprises will be discussed according to four categories: personal characteristics, social impacts, business operations, and service programs.

Critical problems in personal characteristics include entrepreneur leadership, entrepreneurial values and motives, strategic partners, employee quality, internal knowledge sharing, and entrepreneurial intensity. Social impacts include government support, social needs, prospective ideas, environmental sustainability, synergy creation, and positive change. Business operations include market position, organizational culture, partner relationships, financial capital, infrastructure, innovativeness, knowledge transferability, organizational structure, business planning and marketing, and regulatory environment. Finally, service programs include activity design, sustainable product, service delivery, and social ties.

Studies on personality traits have revealed that extraversion positively influences service programs and that openness negatively influences service programs possibly because open people have difficulty focusing on tasks that require intense patience and most social problems cannot be resolved overnight. Neuroticism and conscientiousness positively influence personal characteristics and service programs, and agreeableness positively affects all dimensions of perceived performance of social enterprises.

Research reveals that social entrepreneurs exhibit higher levels of entrepreneurial creativity than commercial entrepreneurs. Studies regarding imaginative capability indicated that although conceiving and transforming imagination are positively related to all dimensions of perceived performance (i.e., personal characteristics, social effects, business operations, and service programs), initiating imagination is negatively related to the dimensions of business operations and service programs. Conceiving and transforming imagination are closely associated with the usefulness aspect of creativity, whereas initiating imagination is strongly related to the originality aspect of creativity. Some interactive relations exist between conceiving imagination and initiating imagination on the dimensions of personal characteristics, social impacts, and service programs. In addition, some interactive relations appear between conceiving imagination and transforming imagination on the dimensions of personal characteristics and social impacts.

Social Entrepreneurial Intention

Increasing focus has been placed on social entrepreneurship worldwide, particularly among the younger generation. Most social entrepreneurs are aged 25–40 years. Scholars proposed empathy, moral judgment, self-efficacy, and perceived social support as antecedents of social entrepreneurial intention. Some scholars have suggested replacing moral judgment with moral obligation; however, recent studies have confirmed that social responsibility can be a better substitute for moral judgment. In addition, research has proposed and successfully tested prior experience with social problems as a robust predictor of social entrepreneurial intention. Recent meta-analytic studies have reported that people with social entrepreneurial intention score high on personality extraversion, openness, conscientiousness, and agreeableness but low on neuroticism. Furthermore, studies have indicated that social entrepreneurs exhibit significantly higher levels of entrepreneurial creativity and risk-taking ability compared with traditional entrepreneurs.

Scholars have critically examined the aforementioned variables and have concluded that prior experience with social problems, perceived social support, and originality in creativity are verified as the most prominent influencers of social entrepreneurial intentions of university students. Particularly, personality traits and prior experience with social problems can predict social entrepreneurial intentions through the mediation of entrepreneurial creativity, empathy, social responsibility, self-efficacy, and perceived social support. Furthermore, originality in creativity, cognitive empathy, and bonding social support have the strongest positive effects, whereas the stockholder perspective of social responsibility has the strongest negative effects on social entrepreneurial intention. Research results have also shown that this mediating model provides different outcomes across academic fields, socioeconomic contexts, and work experiences mainly because of the variances in prior experience with social problems, cognitive empathy, and usefulness in creativity.

Some scholars have focused on this line of research by examining the manner in which perceived potential helps journalists and NPO managers become social entrepreneurs. Research has been conducted on journalists because the skill sets necessary for success as an entrepreneur are a part of the genetic makeup of journalists, whereas research has been conducted on NPO managers because NPOs currently run in an increasingly turbulent context where the operating pressure has become challenging, especially with the slowdown in the global economy. Recent studies have revealed that entrepreneurial creativity, prior experience, perceived social support, social responsibility, and personalities of conscientiousness and openness have determinant influence on the social entrepreneurial intention of journalists. For the NPO managers, entrepreneurial creativity, bonding social support, cognitive empathy, and social responsibility are the major driving forces to becoming social entrepreneurs.

Critically, numerous studies on entrepreneurship at personal and cognitive levels lack contextual hints. However, different regions are heavily influenced by dissimilar cultures. Abundant research at national and economic levels lacks individual considerations. Without elaboration on macrohistories and micro considerations along with their intertwined connections and supplemental explanations, entrepreneurship assumptions may be unwarranted. Furthermore, with growing public concern and support for social entrepreneurship following the global financial crisis, the opportunity and context for such novel developments may now exist; however, public funding is tightly constrained. A key approach is to continually evaluate the extent to which intrinsic and extrinsic interactions of person–context relations are influenced by the unexpected dynamics of upcoming social and environmental problems. The new demand and opportunity for further research on diverse social entrepreneurship topics are currently emerging.

Conclusions

The association between entrepreneurship and creativity has been extensively discussed in the literature. This article provided a comprehensive outline focused on entrepreneurship and the essential phases in the entrepreneurial process.

The global economic environment is volatile, demanding renewed dynamism in the approach employed. Progressive entrepreneurs hone creativity to ensure that their organizations evolve and remain dynamic as well as to please their customers. They understand how creative solutions emerge when they observe and engage and are mindful of their surroundings, through which their business acumen and prospects can be greatly expanded. To maneuver start-ups, every entrepreneur requires passion,

determination, the ability to innovate, and entrepreneurial creativity. Entrepreneurial creativity cannot exist without vision, optimism, and self-disciplined thought, in addition to initiation, tolerance, and persistence from within.

Glossary

Everyday creativity As product, meets two criteria after [Barron \(1969\)](#), *originality* and *meaningfulness*. Can apply broadly beyond “stereotypical” activities in arts and sciences, being relevant to work and leisure, family, relationships, and much more. “Less what does than how one does it.” Everyday creativity has been operationalized by the *Lifetime Creativity Scales* (Richards et al., 2012), with high interrater reliability and multiple indicators of construct validity.

Four Ps of creativity Per Rhodes (Richards, 2018) involves four perspectives on our “originality of everyday life,” including product, process, person, press. Product is the outcome (e.g., object, idea, performance); process, how it is generated; person, the creative individual; press is environmental context. At times, for example, relational creativity, process also becomes product.

Mindfulness Insight-oriented practice involving awareness in the present moment, nonjudgmental, without attachment or preference, with openness, curiosity. Central practice in varied spiritual traditions (e.g., [Goleman and Davidson, 2017](#)), also showing long-term changes in brain. Numerous benefits in everyday life involve stress reduction, peace, calm, health, well-being, and factors in creative openings.

Open systems Involves changeable yet self-sustaining entities (such as any of us); we are never the same, but “autopoietic,” the ongoing result of “self-construction,” a “self-maintaining process by which a system functions to... continually produce the components... which themselves make up the system” ([Mitchell, 2009](#)). [Zen Master Thich Nhat Hanh \(1998\)](#) calls our interconnection in this context “interbeing.” See also [Tarthang Tulku Rinpoche \(1990\)](#). For chaos and complexity, see [Schuldborg, Richards, Guisinger, eds. \(in press\) Nonlinear Psychology](#).

Person-centered expressive arts Process-focused and group interactive multimodal exploration for self-discovery and growth, developed by Natalie Rogers (2009), and incorporating Carl Rogers’ safe environment and client-centered principles (see [Goslin-Jones and Herron, 2016](#)). Interventions can include a trajectory integrating meditation, movement, visual arts, writing, sounding, and more.

Relational creativity Everyday qualities of originality and meaningfulness can be found in rich, present, authentic, interactions between living beings, marked by conscious awareness, give and take, spontaneity, and openness—along with central

[☆] *Change History*: September 2019. Ruth Richards & Terri Goslin-Jones updated the text throughout the article.

This article is an update of R.L. Richards, *Everyday Creativity*, Editor(s): Mark A. Runco, Steven R. Pritzker, *Encyclopedia of Creativity* (Second Edition), Academic Press, 2011, Pages 468–475.

empathy—allowing change and growth in the involved parties. Relational processes can manifest through engagement, authenticity, empathy, mutuality, and empowerment (Jordan et al., 1991; Richards, 2007).

Everyday creative potential offers a universal capacity essential in human evolution. The issue is less “what one does than how one does it” (creative process is more central than product) whether making dinner, reorganizing the office, or painting a canvas. According to humanistic psychologists, creativity can even advance human development to its highest potential.

We seek what we need, and it turns out to be who we are. This article asks four questions: What is everyday creativity? Is everyday creativity healthy? How “normal” are everyday creators? Can people become open more to creative living?

What Is Everyday Creativity?

The “originality of everyday life” on one hand has been vastly important to human welfare and evolution itself, invoking at a level of *process*, a universal capacity to be open, aware, and present, to adapt flexibly, improvise, intuit, shift, try things, and make room for the new. Many people have a “feel” for these universal creative beginnings, but do not notice them, name them, or even think to call them creative. Hence, everyday creativity can, on the other hand, be misunderstood, overlooked, or even invisible. Everyday creativity is less about *what one does* than *how one does it*.

Ubiquitous yet overlooked? Everyday creativity has long been studied by researchers and the benefits identified. A person travels a new way to work or improvises on an oral report they forgot was due. Did they credit themselves with creativity? Researchers recalled an auto mechanic who invented his own tools, an economical homemaker who designed unusual clothes, a parent who engineered a special chair for a disabled son. These participants were studied by Richards, Kinney, Benet, and Merzel, and others at Harvard Medical School and McLean Hospital as they developed and extensively validated the *Lifetime Creativity Scales (LCS)*.

Originality and Meaningfulness

The Lifetime Creativity Scales or LCS operationalized everyday creativity, using interview-based assessments of quality and quantity of real-life creative activity at work and leisure. The dual *product* criteria of “originality” and “meaningfulness” were employed after Frank Barron. Creative outcomes (products, behaviors, or ideas) showed novelty or relative newness (originality), against well-defined rating levels while neither random nor idiosyncratic (thus, meaningful). The popular criterion of “usefulness” was bypassed to minimize culture-bound judgments, meanwhile crediting unusual outcomes where only “time will tell.” The creativity-inhibiting effect of “judgment” was also avoided because of the many possibilities which abound for how creativity may emerge, when viewed as a way of life. (See Kinney, Richards, & Southam, 2012, including the actual LCS). This omnipresence provides an advantage in research with general populations versus groups with a homogeneous criterion (e.g., only artists or chemists or entrepreneurs). For example, one can study participants in an experimental class, or people with ADHD, assessing a wide range of everyday creative outcomes.

Sensitivity training. Researchers began to see “creativity” in areas previously missed, e.g., in home décor, furniture repair, planning a vacation, teaching a class, or leading a fund-raising event. The arts, sciences, and traditional areas of research were also included. Cross-cultural validity was documented when the LCS was translated from Portuguese by Shansis and associates, and used with a Brazilian population.

There are endless possibilities for human creativity, or what evolutionary biologist Dobzhansky called “phenotypic plasticity”—the many ways humans can vary within the bounds of our genetic (and epigenetic) potential. The job of creativity researchers is to capture a variety of outcomes, however unexpected, and to reveal new findings.

The Three Us and Four Ps

If everyday creativity is Underrecognized, Underdeveloped, and Underrewarded—i.e., The Three Us—then it will not be identified, or celebrated at work, school, or home. Instead, one can use Rhodes’s Four Ps of creativity to look not only at the creative *product*, but creative *person* and *process* across diverse populations (who is doing this, and how—and *what is it doing for them?*), and under what conditions (*press* of the environment). These perspectives can also draw from. Runco and Kim (2011) added two further Ps: creative *potential*, on the front end, and later (after Simonton) creative *persuasion*, in a creation’s effects on others.

One Creativity or Many?

Commonalities are also of note. Frank Barron wrote, “Originality is almost habitual with highly creative people” (in Richards, 2018, p.19). Creative *process* and ongoing *person* traits are both relevant, as one responds to life circumstances with originality as a habitual

tendency. This resonates with other “core characteristics” of highly creative persons across fields. Included is Openness to Experience, from the Five Factor Theory of Personality. Hence, “One creativity or many”? According to Amabile, creating can also draw on “something else,” more general across domains, and inviting novelty while giving creativity its “special flavor.”

Broad-based real-life assessment opens research doors. Creativity assessment can be done across many fields. Populations are chosen to study creativity for other reasons, e.g., involving psychiatric diagnosis, childhood experience, special interventions, and to find their “originality of everyday life” wherever it may emerge, in work or leisure. Research studies of creativity and mental health with the broad-based LCS depended on having a broad-based assessment of real-life everyday creativity, however it may emerge, applicable to anyone, in any area—for individuals and also for *families* carrying risk for bipolar or schizophrenia spectrum disorders. This led, with research on well-validated pedigrees of risk-carrying relatives, to important findings stressing *health* as a factor and, for some, potentially, creativity as one of their best medicines. Findings have been supported by other results, in varied and edited collections by Kaufman, Runco and Richards, Goodwin and Jamison, and others. Millions of patients and families may benefit from knowing about: (a) an *everyday* creative advantage within individuals and families at risk, e.g., for bipolar or schizophrenia spectrum disorders, meanwhile (b) linked to *better functioning* (overall, or to certain states), and predicting for *health*.

Is Everyday Creativity Healthy?

Some important areas of health and healing include as follows:

Health and Healing

Verbal and nonverbal creative expression. Pennebaker and colleagues established that expressive writing about difficult and even traumatic issues, for experimental versus control participants, can lead to integration and higher well-being, fewer health center visits, and by contrast with controls *higher immune function*.

Related work in books such as *The Writing Cure* confirmed that verbal expression offered integration and higher working memory. Examples of writing for health and self-development are numerous, including Borkin’s and Cameron’s programs. In addition, there are health benefits from using writing and multimodal expressive arts, included in the work of Natalie Rogers.

Imagery and healing. Achterberg, Freeman, Schlitz, Singer, and others documented the power of imagery to help in healing. Personally created images can work best. For the disbeliever, Freeman even noted how visualization can reduce local blood flow. Jung saw imagery as a powerful mind–body bridge, and imagery has been used for physical problems including cancer, HIV, eczema, and more, plus a range of psychological situations, and in psychotherapy.

Appreciation of creativity. Pritzker discussed active audience engagement, “audience flow,” and healing, and Zausner wrote about the transformative potential within an art audience in Richards’ edited collection *Everyday Creativity and New Views of Human Nature*. Richards noted the power of empathy including roles of mirror neurons. Interestingly, Creative Appreciation has been statistically associated with everyday creativity by Richards, Kinney, and associates. This link may not seem surprising, in a larger *systems context*, where “open systems” are mutually giving and receiving; then sharing and building insights atop and alongside others. Interesting indeed (although interpretations are multiple) are findings by Levy and Langer on *vicarious creativity* for 12,000 people in Sweden, enjoying plays, concerts, and more compared to controls. Among the benefits they *actually did live longer* from their experiences of vicarious creativity.

When Everyday Creativity Is Invisible

Naming Everyday Creativity. It is surely not helpful for creative resilient coping or confidence when one overlooks one’s own potential—and neglects to identify or name personal creative expression. By contrast how wonderful when it is seen, e.g., day-care providers, in vital yet underpaid jobs (some believe salary reflects value), who suddenly realized how profoundly creative and even life transforming their work can be.

See **Table 1** below for misunderstandings about what everyday creativity is and is not.

Everyday origins of eminent creativity. The eminent artist, writer, diplomat, entrepreneur, scientist—people whose work transforms minds, changes cultures can be honored for their creative endeavors. Yet in a larger systems view, there are a wide variety of cultural and creative “niches”; and creative expression has a wider zone in which many people can play. Eminent creativity begins (and continues) at the everyday level, the ground from which it grows. Surely, dynamic creative growth (vs. stasis) predicts for a healthier culture.

Eminence itself derives from a social judgment where the general population, or experts in a field of endeavor, weigh in on excellence. As with Creative Appreciation, an everyday creative populace is more apt to see and accept the new. It is worth considering the 50 million *Cultural Creatives*, studied by Ray and Anderson, moving toward greener, healthier, and more innovative lifestyles, both as everyday innovators and “early adopters.” This picture of creativity and well-being is shaped at many levels.

Misleading negative attributions. Already noted were misunderstandings about creativity and mental illness. Links between personal/family history and bipolar or schizophrenia spectrum disorders *are actually nonlinear, multivariate, and are really about access to innovative material balanced by adaptive functioning*, according to Kinney and Richards, Silvia and Kaufman, and others. Creative benefits go to the better functioning individual—or person at a better functioning time. For instance, according to Kaufman and

Table 1 Everyday creativity: Seven common misunderstandings

<i>Everyday creativity is...</i>	<i>Rather, everyday creativity...</i>
1. NOT an optional “extra” for all but certain famous people.	IS a <i>universal</i> capacity for survival and participation in life.
2. NOT limited only to special areas such as the arts or sciences.	IS found in all parts of life, at work and leisure. “It is less <i>what</i> you do than <i>how</i> you do it.”
3. NOT merely a light and pleasant diversion for relaxation and to fill some time.	IS a vital enterprise involving commitment, flexibility, risk-taking, openness, and can even transform self and culture.
4. NOT an enterprise designed to unsettle and evoke pathology—although sometimes unsettling.	IS one that can go deep into the psyche where it can open, integrate, and heal.
5. NOT an endeavor focused only on creative end-products (concrete outcomes, ideas, behaviors)	IS one involving a healthy open flexible and richly aware <i>way of life</i> which can connect more meaningfully with the world.
6. NOT an activity set apart from much of our being, from concerns, or illnesses.	IS one that reaches deep into mind–body–spirit, and can help passions, and healing, including mind–body healing.
7. NOT a neutral or safe activity that risks little, to the creator, to others, or the social context, and which evokes no inner or outer resistance.	IS a potentially challenging, even dangerous enterprise offering disruption and change—including personal reorganization and threats to society’s <i>status quo</i> .

Adapted from “Everyday creativity—Our hidden potential,” in Richards (2007, 47–48)

Gregoire, factors related to openness (such as low latent inhibition) need to be balanced with executive functions, for adaptive use of creative material.

Creating Toward Higher Purpose

Greater good versus malevolent creativity. Creativity can also be used malevolently—or ignorantly, as discussed in an important edited book, *The Dark Side of Creativity*. (Cropley, Cropley, Kaufman, & Runco, 2010). Yet creativity is a resource that can be turned in many directions—even as a knife can be used to make a salad or to commit a robbery. Some believe, further, that all else being equal, the path of creativity can be a positive and ethically distinguished one, most notably, Combs and Krippner, Eisler, Maslow, Moran, Richards, or Sternberg (See Moran, Cropley & Kaufman, Eds., 2014, *The Ethics of Creativity*). Richards (2014) suggests that creative living by its very process nature can help us become better people. Frequently, creators are open individuals, more fully in the present moment, beyond ego, richly aware, less defensive, in touch with their so-called inner and outer worlds—which are in fact intertwined. David Loye showed how Darwin himself in his last writings saw a positive human caring and collaborative trajectory. Creativity can also be central to a spiritual path, as in Zen arts (See Zen).

Higher humanistic path. Abraham Maslow spoke of creativity as characteristic in the “self-actualizing” person, manifesting as creative *person* qualities. Creativity does not necessarily *lead* to a self-actualizing path, although Runco found an empirical relationship between the two. Yet for persons near the top of Maslow’s (1968) hierarchy of needs: “[Self-actualizing] creativity stresses first the personality rather than its achievements....It stresses characterological qualities like boldness, courage, freedom, spontaneity, perspicuity, integrity, self-acceptance ... (and) the expressive or Being quality” (p. 145).

Awareness and meta-awareness. Creativity invites conscious awareness and the cultivation of meta-awareness. Through self-reflection and mindful awareness, there are opportunities to change consciousness, to reflect on war and peace, to hope, to envision worlds of imagination, and to make creative changes in the environment. Manifesting creativity can influence cultural evolution—and help to write the story of the future. One may encounter the “birth of creativity” and one’s higher human potential. Baron, Ornstein, and others spoke of an “evolution of consciousness.”

Epigenetic doors to compassion and deeper relationship. *The Altruistic Brain* (Pfaff, 2015) built on this potential, with proposed ways to switch on helping qualities or prevent these from being turned off (e.g., by trauma). Pfaff noted how Japanese neuroscientist Atsushi Iriki envisioned supporting neural circuits (“neuronal niches”) so that transitory events, such as training in empathy, can be turned into temperamental traits. The science of epigenetics brings further power—such as awe and humility—since it is not always DNA, but also the environment, which activates certain genes.

Empathy, studied in detail by Judith Jordan (2010), is central to “relational creativity,” catalyzing connections, with authenticity and creativity (showing *originality* and *meaningfulness*), in attunement with others. Empathy is the first step in compassionate action. Davidson’s studies of Buddhist monks showed a “sprawling (brain) circuit that switches on at the sight of suffering.” Pfaff noted this could transport “moral compassion into the domain of ‘neuroplasticity.’”

How “Normal” Are Everyday Creators?

People are ever-changing beings, “open systems” in an evolving dynamic world. Yet if only a few have freed themselves to live with process and flow, might this behavior appear odd to those holding more static views of self and the world?

A different view of “self-in-world.” Lives are in motion. A dynamic view is truer to “real life” than a sense of self as a fixed snapshot. A truer view includes profound underlying interconnections with one another, and evolving identity and activity as part of larger complex systems interacting in a milieu of change and surprise. Chaos theory supplies excellent models of sudden change and creative insight itself. It is significant that science (etc)...is now supporting such larger, and profoundly interconnected views. This is also reflected in the Mind-Life Dialogues between science and spirituality, with His Holiness the Dalai Lama, the most recent from Hasenkamp and White. A forthcoming book, *Nonlinear psychology: Keys to chaos and creativity in mind and life*, edited by Schulberg, Richards, and Guisinger, will further bring home to psychologists in accessible (and nonquantitative) ways, the wonders and potential of seeing more deeply into the nonlinear world. Einstein remarked, “A human being is a part of the whole ... a part limited in time and space. [We may experience our] thoughts and feeling as something separated from the rest This delusion is a kind of prison for us.”

Stereotypes. There are many stereotypes of creators with hair askew and bumping into walls—the absent-minded creator. A message sneaks through that creators may still be a little bit “off.” Imagine if identifications shifted more toward being dynamic processes-in-motion, in a world in flux—where creators lived beyond ego, and risked change.

Dynamic Change, Open Systems

In a more dynamic evolving worldview, where change is the rule, and surprise is expected, might there be both a different norm (central tendency) and wider acceptable range (variability)? For example, storm, election upset, economic boom, viral tweet, emergence of a movement (#METOO). Chaos and complexity theory offers ways to adapt. This picture also resonates with a highly creative personality, open, richly aware, flexible, change oriented, preferring complexity, curious, tolerant of ambiguity, risk-taking, surfing the flow of life.

People are *open systems*, changeable beings who shift and change as they breathe in air eat, listen, engage with media and new experiences. Yet individuals also keep a clear integrity and self-maintenance (autopoiesis) so each will still be recognizable.

How well humans accept such change may depend in part on the views of self. If one rigidly clings to a fixed image or view, then altering it may be difficult. If one instead sees life as a process-in-motion, then change is continuous, and life is more like a video, than a still shot. Humans are explorers, not fixed quantities. Creative individuals may well be willing to make mistakes, as part of the quest, allowing adaptation and learning. If a creator occasionally says or does something “weird” in this process—how else might one generate ideas? This range of exploration is, after all, the everyday creative genius of humanity writ large.

Inner richness. Humans are creative and more likely to be aware and mindful while in touch with the unconscious mind, doing willful “deep sea diving” according to Richards, into the psychological depths while, as stated, accessing executive functions to *balance* this.

On the Myers–Briggs Type Inventory, creators turn inward toward intuition more than outward to a sensory world. This inward turn offers the potential to resist accelerating pressures of the age, less outward reactivity, and moving toward higher intrinsic motivation and inner vision. As Thoreau said that if others do not keep pace, perhaps it is because they hear “a different drummer.”

Opening to Creative Living

The topics discussed below are (1) creative life planning (looking without); (2) expressive arts (looking within); (3) mindfulness meditation (awareness, insight, creative catalyst); and some well-needed (4) rest and rejuvenation.

Life Mapping and Creative Planning

Many people expect creative fulfillment through one area, such as professional work, and neglect other areas of creative expression. Yet even Einstein still found time to play the violin. Daily creativity can be rooted in multiple experiences—being a friend, parent, spiritual seeker, life-long learner, and worker in the world. Escalating demands, time pressures and, societal norms requiring immediate attention pull people away and withdraw energy from their creative visions. This leads to exhaustion and “burnout.”

Shifting priorities. Goslin-Jones’s Creative Living Web (Fig. 1) invites exploration into one’s choices for everyday creativity and growth. Choose 1–2 areas to start. Life can then “become the canvas.” For example, one may choose to become more conscious and intentional by prioritizing time for family life, and a creative passion. Focusing on *relational creativity* and family can bring freshness, presence, spontaneity, and originality to each other, honoring relational goals, authenticity, and mutuality. Or consider an environmental passion; exploring the trends of the Cultural Creatives as described earlier, while pursuing green values, sustainability, and vibrant new ways to live.

Creative Living Coaching. Some people will work with a professional coach. Other people develop their own Creative Living Circles or work with a friend. The coaching process is itself creative, motivational, *raises conscious awareness*, and can help work through times of resistance or dormancy (Goslin-Jones & Richards, 2018).

Figure 1 Creative living web.

Person-Centered Expressive Arts

Person-centered expressive arts (PCEA) was originally used in therapy or for social activism and change, and now in coaching to find new insights and empowerment. PCEA was developed by Natalie Rogers, combining Carl Rogers' person-centered philosophy with the interplay of art, movement, sounding, and writing for self-exploration, with others in a safe and supportive environment (Rogers, 2011). PCEA does not require artistic experience. Combining PCEA with Creative Living Coaching offers a process for participants to explore and integrate choices that enrich life.

Although "expressive arts intermodal" coaching sessions are individualized, it is common to start a session with a mindfulness meditation and to include dialogue about the experience at the end. The process offers multiple sensory experiences and opens one's interior world in novel ways. This results in new insights that are incorporated into a Creative Living Plan.

Mindfulness

Mindful awareness is a practice of openly observing one's physical, mental, and emotional experiences, nonjudgmentally and without attachment, with openness, curiosity, and presence in the moment. Mindfulness (vipassana) or insight meditation is central to progress on many a spiritual path, including Buddhist. It also bears interesting connections with higher creativity. Its benefits include reduction of stress, improving attention, boosting the immune system, reduced emotional reactivity, and promotion of a general sense of well-being.

Even a new meditator, after just 2 weeks, shows better focus, less mind-wandering, and improved working memory. Mindful awareness also strengthens activity of the prefrontal cortex and reduces the fight or flight response. Siegel stressed the opportunity to "pause" which makes space for empathy, compassion, and new ways of responding.

Mindfulness practice has the potential to boost creativity-linked openness to experience, "tolerance of ambiguity," and cultivation of nondefensive and nonconforming behaviors. Practitioners may show greater awareness of others and the world at large. Heart and compassion-based meditations can build on this, enhancing empathy and a greater neural attunement with those who are suffering. Some inner-focused mind states, with slower EKG frequencies, as shown by Austin, are not unlike those during insight stages of creativity. Such restful states, and a need for incubation in creativity, as in Wallas's 4-part creative process model of *preparation-incubation-illumination-verification*, support value for everyday creators in taking time for rest and rejuvenation.

Rest and Rejuvenation

The high volume of work and the 24/7 culture cultivates overstimulation and anxiety. This can spiral into physical and emotional exhaustion, problems with sleep cycles, and depression. Some people also experience burnout, depleted energy, exhaustion, and lack of motivation. Even those passionate about their life and work can feel hopeless, drained, or overreactive. In one study, the average person checked their cell phone every 6-1/2 minutes. Some vulnerable people even show brain signatures of addiction to the overstimulation of cell phones and technology.

Many traditions formerly practiced a day of rest and reflection. Families and communities gathered for meals. Everything slowed down. Work stopped. Today, in daily life, taking short breaks is an important habit for encouraging the quality of life and creativity. Energy can be restored by pausing, experiencing silence, and reconnecting with one's inner rhythm. Creativity can be cultivated mindfully with a customized living plan, meditation and rest, toward living a life with zest and passion.

Conclusion and Breath as Metaphor

People are always changing and developing. *This* is human creativity, and the evolutionary process—to explore and to grow, not to preserve some stagnant *status quo*. Individuals are open systems, breathing in food, air, information, life, and energy. People engage the new, stumble and soar; both are important types of feedback. At times, creators may look weird, at other times brilliant. Always, people are in motion and profoundly interconnected. Everyone is truly co-evolving together while co-creating something that they may not yet even begun to imagine.

The Four Areas

The time for risk and creative transformation is *now*. To review:

1. *EVERYDAY CREATIVITY*—Time to see it, consciously to give and receive the meaningful originality of everyday life. As lenses, the Ps of Creativity are guides.
2. *IS IT HEALTHY?* Profoundly, at best, with presence, openness, physical and psychological benefit, e.g., toward resolving conflicts, connecting, mind-body healing, finding higher purpose.
3. *WHAT IS NORMAL?* Diversity, awareness, dynamic change, risk-taking, spontaneity, and presence are qualities to be celebrated. In the future, static conformist norms may seem pathological.
4. *OPENING TO CREATIVE LIVING*. Life is the creative canvas. Creative life planning was explored, aided by expressive arts, mindfulness meditation, and rest and rejuvenation.

Symbol and Metaphor as Summary

One may conclude with attention to breath as metaphor, to breathing in/out, in resonance with an evolving and creative self-in-world, changing, dynamic, alive, visionary, and always active. Research support exists, e.g., from Skarda and Freeman, regarding new mental chaotic “attractors” for scent—spurred by inhalation and formed in exhalation. Buddhist teacher Thich Nhat Hanh suggests, (In-breath) “I am ...” (Outbreath) “Calm and relaxed.” Effects link to mindful awareness, creative states, and chaos and complexity phenomena. Similar to ocean waves, there is a ceaseless process of dissolution and creative renewal. Rieker (1971) offered a pranayama perspective:

Inhalation brings with it the sense that one is absorbing something tangible ... and thereby dissolving it....Now exhalation follows A whole world seems to emerge, fashioned completely from vibrations then that feeling of happiness Thus the pendulum swings from breath to breath, from creation to dissolution and ... back to creation again. (pp. 94–95)

The in-breath resonates with *preparation* and *incubation* in Wallas's model of creative process; the out-breath, with *illumination*, and *verification*. Birthing the new is a big part of the everyday human job—at time a job for “upstarts” and not always socially welcome—however, it may also be a joy and shining challenge in everyday creative life.

Glossary

Authenticity A characteristic of a person who demonstrates creativity—"authenticity" literally means "author of values." The person who demonstrates creativity must form new principles, new heuristics, make new connections, and open new worlds.

Constructionism The belief that the person who creates participates in choosing and shaping the surroundings within which the work proceeds, the skills needed for the work, and the definition of the ensemble of tasks—the person must take possession of whatever is needed for the work.

Constructive repetition An important organizing principle proposed by Gruber—the central theme is that creativity, mastery, and meaningful repetition have an important connection. For example, da Vinci sketched over one thousand hands before selecting the version he used for the "Mona Lisa".

Facet Any aspect of a creative case that can be made sufficiently distinct to permit intensive study of it, whether regarding process, product, content, or context.

Initial sketch The creative person frequently begins work on a project by making a quick and crude sketch of the work to follow.

Intrinsic and extrinsic motivation Intrinsic motivation occurs when the considerations impelling a person to do a certain project are inherent in the nature of the work, either as a process or as product. Extrinsic motivation occurs when the motivating considerations are different from the nature of the work. The two kinds, although usually contrasted with each other, are not necessarily incompatible.

Network of enterprise Creative work can be viewed as organized so that enduring enterprises are composed of several projects, and to carry out a project requires engaging in several tasks. The whole assembly of a creator's enterprises is a network of enterprise.

Pluralism An attitude guiding the investigator, welcoming and looking for the many rather than the one or two essentials. Thus: many metaphors, many insights, many mentors, many motives.

Purpose An essential system of the "evolving systems approach"—the creating person requires the ability to see vividly into the future, to have a sense of mission, and to designate a network of viable strategies to ferry one's self to the desired goal.

System The way in which the elements comprising an entity are interrelated or organized into a functional whole. It is usually intended that the elements do not completely lose their identity when participating in such an arrangement.

Introduction

The Evolving Systems Approach (ESA) is both a method and a theory created by Howard E. Gruber. ESA is designed to study and understand creativity. The focus of ESA is for understanding the uniqueness of the individual creative person at work. It involves no commitment to discovering generalizations one can make about all creative people. Its primary aim is to construct an account, both

[☆] *Change History:* August 2019. Jan Stahl updated the text throughout the article.

This article is an update of J.M. Stahl, R. Brower, Evolving Systems Approach, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 476–479.

analytical and developmental, of each creative person considered and to arrive at what may be called a “theory of the individual.” “Developmental” does not mean an account starting with infancy, but one that starts wherever it is feasible. Fortunately, many productive creators usually leave ample traces of their work. The evolving system comprising the creative person includes three major subsystems: knowledge, purpose, and affect. Creative acts are taken to be outcomes of the functioning of this system, and every episode and every facet of the process of creative work engages all three subsystems.

ESA has the following points of emphasis:

1. The approach is developmental and systematic. ESA views creativity as the result of protracted, hard work over long periods of time.
2. The approach is pluralistic. The person who creates exploits many insights, projects, social relations, and educational sources. ESA identifies three essential, wedded systems that give rise to creative production: purpose, affect and knowledge.
3. The approach is interactive. The person’s work is always conducted in relation to the work of others.
4. The approach is constructionist. The person who creates must reconstruct the elements of a medium to bring a vision to fruition.
5. The approach is existentially, experientially, and phenomenologically sensitive. The person who creates is not considered simply as the maker of the product, but additionally as an active person in a world. He or she is literally living in a medium.
6. ESA proposes that an understanding of creative work requires a conception of the person as an evolving system in an evolving milieu. Each person-as-system is comprised of three sub-systems: organization and application of knowledge, a sense of mission and purpose, and a rich affective domain. Each of these subsystems has a dual aspect; in one way it has an integrated life of its own, in another way it contributes to the internal structure of the person’s other systems.
7. The preferred methodology of ESA is the case study. The case study method has a venerable tradition in psychology. It was employed with great effectiveness by such luminaries as Rudolf Arnheim, Sigmund Freud, Jean Piaget, Gordon Allport, Erik Erikson, Jean-Marc Gaspard Itard, Hermann Ebbinghaus, and Alexander Luria. Each made their ground-breaking discoveries through the in-depth exploration of relevant case studies.

One of the important facets of the case study is the initial sketch, which seems to occur in many if not all instances of creative work. For example, when Picasso began the month long effort that produced the great mural *Guernica*, his first move was a small, rather primitive sketch to which he referred repeatedly in the month that followed. Later, other facets of the creative case study will be discussed. For the moment suffice it to say that each new starting point serves as a search-light that reveals new configurations and as a gyroscope that keeps the creator pointed toward remote goals. In this way, selecting a new starting point permits the creator to maintain a freshness of his or her work. In practice, history and evolution guarantee that such new starts will recur incessantly.

If we do no more than vary the starting point of each study, other changes follow so that each new starting point reveals new facets of the creative process. Consider two contrasting points of view: the psycho-biographer approaches the case with the primary aim of understanding the historical and personal factors that set the stage for the creative process, without actually examining in any detail the creative work itself. On the other hand, the experimental psychologist interested in creativity, in order to have a manageable experimental design, narrows the focus of attention drastically and increases the number of subjects. The psycho-biographer typically pays little attention to the process of creative work; the experimenter relaxes the criteria used in selecting creative subjects (e.g., the more creative half of an ordinary high school class) in order to have enough subjects to complete the experimental design. Taken to an extreme, the assumption underlying much of this experimental research is that everyone or almost everyone is creative to some degree, and we can consequently study the process in the less than great even if our aim is to understand the higher levels of creative endeavor.

By a system we mean a set of distinct components with specified relationships. A simple list of traits is a kind of theory because it proposes to say what is important, but it is not a systemic theory. Only when we examine interrelationships of these members of the system can we begin to speak of systems. Systemic analysis is possible at many different levels, for example, the organism is composed of organs and society is composed of organisms. To choose as one focus of attention a particular level of analysis, or set of levels, need imply no denigration of other levels of their students.

Organization

In the present context, the idea that organization and adaptation are twin aspects of creative evolution could also be described as forces making for stability and forces making for novelty. In the study of creativity, as in all other living processes, there must be continuity and stability.

There is a confederation of scholars interested in creativity, such as genetic epistemologists, Gestalt psychologists, and system theorists. Some researchers in each camp claim superiority for their brand. Each of these approaches can be considered as high-lighting some important aspects of the whole process, their totality providing the context for anyone of them.

One of the cardinal concepts of ESA is “pluralism.” At any given historical moment there are several schematizations available to the person, and they can be selected, composed, and arranged in different ways. The principle of pluralism proposes several schematizations, multiple metaphors, and many enterprises are examined, explored, exploited, redefined, fused, and synthesized with the person’s current and evolving vision and body of knowledge.

At times, the discipline of psychology seems to present a puzzling spectacle. Some of the same controversies crop up in every generation, such as the conflict between holism and atomism, or that between evolution and stasis, or that between sudden intuitive leaps

and incremental change. In 1937, the prominent personality psychologist Gordon Allport wrote, “It is not upon the cell nor upon the single organ, nor upon the group, nor upon the species that nature has centered her most lavish concern, but rather upon the integral organization of life processes into the amazing stable and self-contained system of the individual living creature” (1937, p. 3).

It may be that these repeated controversies stem not from blind commitment to one or another ideology, but from the legitimate necessity to rework fundamental concepts as circumstances change. Allport argued emphatically and at length for the necessity of studying the single case and to point out the various tendencies, in the psychology of that period, to escape from the trap of atomistic, individualistic positivism.

Facets

It is common in psychological research to distinguish between “how” questions and “why” questions. “How” addresses itself to the processes of creative work; “why” asks, what are the underlying reasons for doing it? To a large extent the failure to separate the two kinds of questions has led to profound neglect of “how” questions. An important movement in the study of creativity has been psychobiography, which is the application of personality theory, especially Freud’s, to understanding creative people. A related effort, psychohistory, applies the same range of theories, not to understanding the individual creator, but rather to historical events for which a psychological theory is proposed. Insofar as these approaches delve deeply into the life of a creative person, they are of very great interest. Unfortunately, to a large extent psychobiography and psychohistory have been the occasion for neglecting “how” questions. Insofar as these approaches draw upon the early years of the creator they are forced into undocumented speculations. A third category of creativity research is the psychometric approach, in which tests are administered to large enough numbers of subjects to permit statistical analysis. For different reasons these three methods all avoid studying the creative person at work. On the contemporary American scene there has been a shifting focus on:

- Birth order effects, in which the person becomes creative because of his or her special place in the developing family.
- Bipolar disorder, where the anguish of private life provides the stimulus for creative expression.
- Metaphor, where the ability to see and express commonalities between unlike things is the central ingredient of creativity.
- Great powers of visualization.
- Divergent thinking, the ability or propensity for thinking of unusual responses.

All of these and many more have been singled out as the essence of creativity.

Paradoxically, ESA avoids a singular focus by welcoming all such proposals into the tool shed. However, the uses to which the tools will be put vary from project to project and different creators may accomplish similar ends with different collections of tools. For example, the physicist Richard Feynman solved an important class of physical problems with theoretical tools quite different from those used by others in solving the same problem. Feynman’s method was geometric and the others’ was algebraic. While in this instance Feynman’s method eventually prevailed, the work of the others was also creative. Moreover, the creator does not use one pre-fashioned tool but a collection of them, including some that are invented in the course of work on each project.

From the creator’s point of view, a given facet or facets may be foremost in attention, the vast remainder being the background. The distinction between figure and ground is well known in the psychology of perception. A change in attention may be thought of as a figure-ground reversal. If the figures in question are cherished projects, the creator may experience mixed feelings at the new engagement together with regret at what is left behind. The ground, or context, is so complex and dynamic that new facets are continually appearing. For example, after Charles Darwin published the *Origin of Species* he took up with great vigor questions of physiological botany that had long lain fallow in his network of enterprise. This move brought a certain closure to his work: nearly a century before, his grand-father Erasmus Darwin had written much on botany. Of particular relevance was his long scientific poem, “The Love of the Plants,” which the young Charles Darwin greatly admired but never emulated.

Insight and Problem Solving

There is a widespread belief in the prevalence of sudden insights arrived at intuitively, such insights constituting the genuine article, a creative product. An often retold and celebrated story is August Kekulé’s account of his discovery of the benzene ring, which he made while half asleep on a London bus. However, if his account is read carefully one can see that he had been moving in that direction for well over a decade, and the dance of the molecules that he described was not a unique event, but a mode of thought that he employed in his chemical thinking.

The reverie on the bus must be seen in its larger context, the general nature of Kekulé’s thinking. Moreover, his thinking must be seen in the still larger context of the history of chemistry in the 19th century. Viewed in these lights, Kekulé’s epiphany was not a miracle of intuition, but the product of protracted and directed work by a network interested in structural chemistry (See Intuition).

If insight is not the cause or the embodiment of creative work, what is its role in the creative process? First it should be said that insight, when it does occur, takes a variety of forms. As the culmination of a protracted process it may be a sudden change in awareness, or it may be a gradual shifting in point of view. With this in mind, there is no great need to define insight a priori: the process is

to study the record, note changes, and describe them (sudden or gradual, aware or unconscious, pursued immediately or bracketed for later attention).

Purposes and Motives

A sharp distinction widely agreed upon is made between intrinsic and extrinsic motivation. The former refers to the self-satisfaction sought in actually engaging in creative work. The latter refers to the satisfaction arising out of recognition, prizes, monetary awards, and the power that comes with fame. With regard to intrinsic motivation there is distinction between the satisfaction derived from engaging in the work and that derived from completing it. On the surface it might appear as though extrinsic motives correspond to “why” questions and intrinsic motivations to “how” questions. But if we take the creator’s network of enterprise as a whole as reflecting the totality of his or her intentions, absorption in this set of tasks becomes a powerful motive.

Beginning work on a task sets up a kind of drive for completing it. The question remains open whether this drive is the same as the pleasure in actually engaging in the work. It may well be that in real creative work, both kinds of satisfaction are at work under the broad heading of intrinsic motivation. Meanwhile, it is reasonably clear that extrinsic motivation is also important. Nobel prizes and other blandishments are ever present and highly visible. A plausible hypothesis is that, for whatever reason, at moments when one is not engrossed in the work, extrinsic motivation drives the creator back into it; when he or she is engrossed, the very same extrinsic motives may be a distraction, even a pollutant: intrinsic motivation takes over. In Darwin’s notebooks there are few passages indicating extrinsic motivation, but there are some. And it should be remembered that writing the notebooks was itself part of the work process, a record of activity governed by the task, not of activity governed by other considerations. On the cognitive side belief systems evolve throughout the life history, and on the intentional side motives evolve.

Tasks are not undertaken singly. Each task becomes a member of one or more enterprises. These, taken together, form a network of enterprises, and this network can be thought of as the individual’s evolving organization of purpose. This network of enterprise, once formed, serves to locate any given project within it; at the same time, it represents a large portion of the individual creator’s self-concept. Every task may be said to have a history. A gap, disequilibrium, or unsatisfactory situation is observed; this leads to the undertaking of a task. Some subset of such tasks forms an enterprise. Seen in this light, an insight need not be the solution to a problem; it may be the initial recognition that one exists. Often, the recognition of a problem unsolved, a voyage not yet taken, can produce the thrill of discovery that we usually associate with solution (See Problem Finding).

Skill

Studies of persons who demonstrate creativity indicate convincingly that it is important to develop a level of expertise for a domain as a necessary foundation for subsequent creativeness. Astonishingly high levels of skill account for high levels of creativity. But there are many individuals with great skills who are not very creative. For example, among artists there are greatly skilled copyists and plagiarists who can successfully imitate at least one artist and sometimes many. Such individuals become the plague of museum curators, who for all their expertise sometimes fall victim to artistic fraud. So skill alone is not sufficient for creative work. On the other hand skill is certainly a virtue which may be attainable through practice.

Collaboration

Growing out of the extreme individualism of modern Western society, the picture of the creator as a lonely genius is very widespread, but collaborative processes are also important. For example, there is the well-known case of Albert Einstein and the Olympia circle, three young men who met every week over coffee to share ideas. Thus Albert Einstein, during his years working in the Swiss patent office, was not, as is sometimes suggested, alone in his theoretical quest. He had important collaborative opportunities. Another example is the case of Pablo Picasso and Georges Braque, who together invented and initiated the important movement in art of cubism. Other examples include Vincent van Gogh and Paul Gauguin, Dudley Warner and Mark Twain, Orville and Wilbur Wright, Marie and Pierre Curie, and on and on. Most creative people have significant collaborations during some phase in their creative development, whether it be with teachers, peers or heroes.

Even in the case of the project that is conducted alone, one almost invariably finds that the individual creator is in some kind of fruitful relation with others. Van Gogh, for example, sent his canvases to fellow artists all over Europe and received theirs, providing a rich language for aesthetic discourse, the work itself. Gauguin and van Gogh lived together in Arles, France, working side by side and simultaneously dreaming of a utopian artists’ community. Mythically isolated creators such as Isaac Newton, Emily Dickinson, and van Gogh profited from collaborative relationships. To these examples should be added informal groupings such as the *Salon des Refusés*—artists who were rejected by the French artistic establishment, but nevertheless managed to construct relationships of mutual defense and support.

Conclusion

Post-Grubarians are approaching a well-founded, well-integrated theory of creativity that is both descriptive and prescriptive. Creativeness rises and reaches fruition from the viable pluralism of five evolving systems [1] a rich store of domain-relevant knowledge, [2] the cognitive ability to rearrange and recombine the elements of a domain in service of a synthesis and insight, [3] high levels of motivation to work hard over long periods of time, [4] a sense of purpose, [5] ability to benefit from collaboration and to benefit from exposure to the ideas of other. It is possible to study an individual in detail without raising individualism itself to cult status. Unique people, which we all are, can work together. Creative work always takes place in a multifaceted environment. There is no necessary conflict between respect for the individual and sensitivity to the social nature of all creative thought.

Expertise

Expertise refers to the cognitive, perceptual-motor and physiological mechanisms that allow experts to consistently attain superior levels of performance when encountering representative situations in activities in their domains and/or produce new achievements or products valued in the domain of expertise. Webster's dictionary defined an expert as "one who has acquired special skill in or knowledge of a particular subject through professional training and practical experience." Accordingly, typical experts are individuals such as medical doctors, accountants, teachers and scientists, who have been certified as professionals after extended training and have then accumulated experience in their specialty. More recently, the term expert has been expanded to describe any highly skilled performer who exhibits superior achievement after instruction and extended experience in a field. Among those fields, which are called domains, are the arts (e.g., music, painting, and writing), sports (e.g., swimming, running, and golf), games (e.g., chess, SCRABBLE, crossword puzzles, Othello, and bridge), and professional activities (e.g. medicine, nursing, and business). Because the structure of the mechanisms mediating performance of experts in different domains share certain characteristics a single concept, namely expertise, refers to the associated phenomena when they are demonstrated in different domains. Also, experts' superior performance require domain-related experience and thus develop in a similar manner across domains. As the level of achievements gradually increase it is expected that the quality of performance, the value and originality of crafted products, and the adaptation to situational demands will increase and reflect higher levels of mastery and creativity. Thus, high level of expertise and creativity are closely related and both reflect the highest levels of domain-specific achievement.

Overview: Expertise and Expert Performance

The main task for researchers of expertise is to explain how some individuals are able to attain the highest levels of achievement in a domain, and why there are only so few who reach these superior levels. In order to be able to attain very high (expert) levels of performance in domains of expertise, both nature and nurture must be involved. Experts' performances often look effortless, and their most refined and insightful behavior is generated rapidly and naturally rather than being the result of prolonged deliberation. One is thus led to believe that experts excel based on general basic characteristics, such as intelligence, memory, speed and flexibility. It has traditionally been assumed that those general characteristics are impossible to train and thus are determined to a large degree by genetic factors (nature). Everyone agrees, however, that experts must acquire at least some necessary domain-specific knowledge and skill (nurture). The relative importance of nature versus nurture for expert achievement has been discussed for many centuries. A

couple of questions have been the primary focus. First, how does expert achievement develop and what is the role of instruction and training? Second, are people born with certain characteristics to attain expert performance or are those characteristics acquired as a consequence of training? This entry will briefly review the most important conceptions of expertise spanning the last centuries, then turn to a summary of our current knowledge, and finally outline the implications and connections of expert performance for genius and major creative innovations.

The Traditional Account for Expertise, Expert Performance, and Exceptional Achievement: Innate Talent

Beginnings in the 19th Century: Sir Francis Galton

In his pioneering studies of excellence in 19th century England, Sir Francis Galton found that a very large number of the most valued achievements were made by members of a small number of eminent families. Galton found that as the genetic similarity between relatives decreased, the likelihood that individuals had outstanding reputations also was reduced. To explain how individuals from these eminent families could succeed in such diverse professions as politics, literature and science, Galton claimed that instruction and training were beneficial, and associated with large initial improvements of performance. However, with further experience the associated improvements in performance became increasingly smaller and eventually a rather fixed upper bound for performance was attained. Galton (1869/1979) thought that upper bound was limited by individuals' basic mental capacities which could not be modified through training and experience. The rare occurrence of expert performance could thus be explained by the small number of individuals engaged in the domain who were genetically endowed with superior basic capacities allowing them to succeed. Consequently, Galton and many other contemporary psychologists and educators developed psychometric tests to measure basic capacities of memory, perception and thinking. In those tests the influence of knowledge and prior experience was intentionally minimized. Through extensive testing of children and adolescents, investigators hoped to identify innately talented individuals who, given the necessary resources of training and support, were most likely to achieve high levels of performance.

Is the Importance of Innate Basic Capacities Overrated?

Today, over a century later, it is safe to say that past efforts to measure individual differences in basic capacities did not succeed in successfully predicting future expert performance or even identifying adult experts. For example, when athletes or other experts were tested in the laboratory on how fast they can respond to the onset of a light (simple reaction time), they were not systematically faster than other subjects. The superior speed of tennis players' movements allowing them to successfully return a fast tennis serve must thus reflect an acquired ability to respond rapidly in representative situations rather than a general superiority of speed of neural impulses. Similarly, chess experts can recall nearly all the over twenty chess pieces in a typical chess position (taken from a chess game) after a brief exposure, whereas beginners in chess can only recall around four or five pieces. Yet, if the chess pieces have been randomly arranged, then the advantage of the experts over beginners is dramatically reduced and experts recall is sometimes not even statistically different from the novices. Both the chess experts' and athletes' superior abilities are primarily evidenced in representative situations encountered in their domain of expertise, and therefore the individual differences in their performance in the domain are not consistently correlated with the basic capacities measured in the laboratory.

In recent reviews, the major differences between expert performers and less proficient individuals have been found to nearly always be consistent with specific adaptations acquired by the experts during their lengthy training. This holds true for many anatomical and physiological characteristics of athletes such as the size of their muscles, the size of their hearts, and the flexibility of joints; and for the increased range of mobility of the limbs in ballet dancers and musicians.

Recent research reviewed by Merim Bilalić and Guillermo Campitelli (2018) also showed dramatic differences in the brains of experts with differences reflecting the activities in the corresponding domains of expertise. For example, structural changes in the brains of musicians are correlated with the length or early onset of training. Other adaptations "described by Ericsson (2018) involve" for example the increased thickness of the bones of the playing arm (but not the other arm) of tennis players, or the optimization of oxygen absorption of runners only at certain levels of running intensity. Finally, most physiological adaptations reverted back to normal values once training was stopped or dramatically reduced at the end of athletes' active careers, which is clearly an indication of their acquired nature. However, at least in one instance, namely height, certain that genetic factors independent of experience and training play an important role for the attainment of expert performance in domains, where more height constitutes either an advantage (e.g. basketball) or a disadvantage (e.g. gymnastics).

The incidence of expert achievement in some famous families, such as the Bach family with many famous musicians, is frequently cited as proof for the high heritability of special talents. However, recent reviews of this evidence have questioned such claims. Instead, the early start of instruction of children initiated by parents with musical skill and access to networks and specialized training seem to offer sensible alternative accounts. Because expert performers are so rare, it is very difficult to conduct rigorous studies of heritability. So far, the small number of published studies on experts (i.e. Olympic athletes and musicians) has been unable to document any significant heritability of expert levels of performance. Heritability studies rely mainly on data from individuals who shared the same environment during upbringing (adopted children), and from those who shared genetic material (identical twins, fraternal twins or siblings). Unfortunately, those individuals are surprisingly underrepresented among individuals

reaching expert levels of performance, which makes estimation of heritability of expert performance extremely difficult with those methods.

The Alternative Account: Expertise as Acquired Knowledge and Skill

Acquiring and Organizing Knowledge for Use in a Given Domain

One of the most significant advances in our understanding of expert performance resulted from a direct comparison of the thought processes of experts and less accomplished individuals. In the 1940s researcher [Adrian de Groot \(1978\)](#) gave a pioneering account of the thought processes that allowed world-class chess players to consistently find better chess moves than less skilled players. He instructed chess players of each group to think aloud while they selected their next move for a given chess position. The resulting “think-aloud protocols” revealed that all chess players were quickly retrieving promising moves from memory while examining the organization and structure of the presented chess position. Then, during the process of evaluating these potential moves by searching and planning, even better moves were often discovered. Neither de Groot nor other subsequent researchers found evidence that elite players scored higher on tests of IQ or general cognitive ability or that their speed of processing tasks unrelated to chess differed from those of less skilled chess players. The primary difference between the chess players was that the world-class players were superior in evaluating and reasoning about possible chess moves and generating corresponding moves.

According to the cognitive psychologists Herbert Simon and William Chase, who extended de Groot’s work, expertise is an extreme case of acquired skill. Their view is thus in agreement with general theories of skill acquisition in which knowledge is first acquired and then organized into adequate procedures and actions. With continued practice, individuals become increasingly able to access more appropriate chess moves automatically and speedily through pattern-based retrieval. By recognizing complex configurations of chess pieces, [Simon and Chase \(1973\)](#) argued that an expert can retrieve good moves from his memory of related chess games. Their theory was also able to explain the chess experts’ superior memory for briefly presented chess positions. Also, the availability of complex chess patterns in the long-term memory could explain why they recalled many more pieces from presented positions from actual chess games than less skilled chess players. However, randomly rearranged configurations reduced the advantage of the experts over the less skilled players to a few pieces, because the random configurations would not match the experts’ body of already stored patterns.

Highly organized knowledge was also proposed to be a key factor in expertise involving more traditional, academic activities, such as solving textbook problems in physics. When physics experts (professors) read through a physics problem, they first understand the described situation and when reading the question they can easily generate the steps necessary for computing the answer. In contrast, non-experts (novices such as beginning college students) typically look for the question at the end of the problem first and then retrieve formulas that relate the desired quantity in the answer to the information given in the problem. At that point they can fill in the values and compute the answer. Their general method involves working “backwards” from the requested answer. As one would expect, physics experts not only had more knowledge than novices, but as researchers Micheline Chi and her colleagues ([Chi, Glaser, & Farr, 1988](#)) found, they also organized it around relevant theoretical principles of physics. This allowed the experts to retrieve plans for solving the problem directly as part of their understanding of it. In contrast, the physics knowledge of the novices was poorly integrated and based on superficial appearance of objects, such as pulleys, springs, and inclined planes, rather than deeper concepts. Consequently, the superior ability of Physics experts to reason and solve problems appears to be specific to material related to their domain of expertise. More generally, studies showed that experts in chemistry and social science lacked the special knowledge and strategies to successfully analyze a problem in political science; experts in experimental research were found to be able to design experiments of superior quality only within their particular area of research specialty.

All these results support the general notion that experts’ superiority is closely linked to their superior accumulation of knowledge relevant to the encountered situations during activities in the domain. This suggests the possibility that one could extract the experts’ knowledge and use it to build computer programs, so-called expert systems, which might behave like a human expert. A number of researchers, especially during the 1970s and 1980s, took this knowledge-based approach to expertise and designed methods to elicit the knowledge of the experts, and then described the structure and organization of their knowledge in the specific domain. However, the massive amount of relevant knowledge and methodological problems of extracting knowledge and implementing it in computer models have continued to present major obstacles to the expert-systems approach to expertise.

Challenges to the Knowledge-Based View of Expertise

Once psychologists in 1970s and 1980s became interested in expertise, they searched for domain experts. To their amazement, some “experts,” with lengthy education and extended experience, did not exhibit a performance superior to less experienced individuals or even novices. For example, professional stockbrokers were not found to be consistently superior in selecting investments when compared to random selection of stocks from investment indexes. Similarly, psychological therapists with a PhD and many years of clinical experience were not more successful at helping clients than less experienced therapists with much less advanced training. The most consistent dissociation between level of expertise (indicated by the amount of schooling and experience) and observable performance was demonstrated in many types of expert judgment, especially in medicine and nursing.

With experience, individuals generally increase their performance for a limited time until they have reached an acceptable level of performance. Further improvements beyond this point are unpredictable. For domains such as medicine, nursing, computer programming, auditing and sports, the number of years of work experience has been repeatedly shown to be a poor predictor of

attained performance. Thus, it cannot be taken for granted that all highly experienced and knowledgeable individuals (experts) will actually exhibit superior performance. For scientific purposes, objective evidence for their superior performance is therefore indispensable.

Identifying Experts' Superior Performance

How can superior performance be measured, if mere social recognition of expertise does not always yield scientifically reliable evidence for such superiority? If expert performance is defined as a reliable superior performance in a domain, then the first step is to ensure objectively that all the studied experts actually exhibit this performance under controlled conditions. By defining expert performance as a reproducible performance which is superior to that of most other individuals in the domain, it becomes an observable empirical phenomenon that can be measured independent of any theoretical framework. It now becomes possible to analyze the phenomenon experimentally and compare alternative theories of its structure and acquisition. For example, researchers can try to find out whether or to what degree the performance requires innate talent or if it can be explained with skills acquired through extended experience and training.

Objectively measuring performance of individuals is difficult, and most domains have developed and refined relatively standardized methods for assessing the level of achievement. Virtually every domain focuses on independent and reproducible performance of participants in the domain. In the simplest case, different performers perform the same task, such as athletes running 100 yards during a competition, and the performer with best performance for an event wins. In other domains, such as chess and tennis, the outcomes of many pair-wise competitions allow the computation of a ranking of all the participating performers in the domain. In the arts, sciences, and some sport events, a panel of experts or judges evaluates and agrees on the quality of individual performances or specific achievements. Those achievements can be artifacts, such as paintings, compositions, recordings, books or articles that are ultimately recognized as major creative contributions and innovations. In sum, the evidence from the measurement of expert performance shows a general superiority of experts that need to be consistently demonstrated (reproduced) under many different conditions. Next the findings regarding the importance of experience and practice for attaining consistently superior levels of performance will be discussed.

The Need for Extended Domain-specific Experience to Reach High Levels of Performance

Recent reviews show that long-term engagement in activities of the domain or related domains is absolutely necessary to attain expert performance. When the skill development is studied over longer periods of time as in longitudinal studies (see Fig. 1), there are no sudden increases in performance from one point of time to the next. For example, even child prodigies in chess show a gradual yet steady increase of their performance over time, when they compete against adult players in chess tournaments. Also, expert performers continue to improve their performance long into adulthood. They typically reach the highest (peak) performance of their career at ages from the mid to late 20s for many vigorous sports and from the mid to late 30s and 40s for the arts and sciences. The extended development past physical maturity, illustrated in Fig. 1, implies that experience is necessary for improving performance.

Finally, the most compelling evidence for the necessity of extended experience is how long it takes even the most talented individuals to reach an international level after their start of engagement in the domain or related domains (see Fig. 1). In their influential theory of chess expertise mentioned earlier [Simon and Chase \(1973\)](#) proposed the “ten-year rule”, because they observed that no modern chess master had ever reached the international level in less than around ten years of playing chess. Although there are now several recent exceptions to that rule for young chess players, the fact remains that everyone needs well over five years and nearly everyone more than ten years of concentrated engagement in domain-related activities before winning at the international level in chess. Results from domains of expertise other than chess, such as music composition and a wide range of sports, science and arts, are consistent with this modified ten-year rule. However, the vast majority of individuals who reach such high levels take

Figure 1 An illustration of the general performance trajectory of elite chess players as a function of age. The international level, which is attained at around 10 years of involvement in the domain, is indicated by the horizontal dashed line.

considerably longer. For example, winners of piano competitions have typically spent over twenty years of concentrated training. In sum, the necessity of active engagement in domain-related activities in order to improve performance in a domain of expertise is well established.

Mere Experience Is Not Enough – The Role of Deliberate Practice and Teachers

When individuals start to engage regularly in a leisure activity, such as playing tennis or golf, or begin to work in a job/profession after finishing school, they initially go through a limited period of relatively rapid improvements. During this time obvious mistakes are corrected. Once they reach a satisfactory level of performance further increases are usually not clearly noticeable. Most people have experienced this phenomenon of a stable level of performance in spite of long-term active engagement in a domain. Consistent with this cessation of improvement, the length of experience in the domain has been found to be, at best, a weak predictor of current level of performance in a wide range of domains, such as sports, medical diagnosis, psychotherapy, and accounting. If additional experience does not automatically change individuals' behavior, what does?

When actions and activities run smoothly, the structure of performance becomes habitual and thus remains essentially unchanged. Even if mistakes occur, such as when a novice tennis player misses a back-hand volley during a game, the other players are not willing to stop the game and give the player chances to train on similar shots. Moreover, this shot is so rare, that the next encounter with a similar shot may well occur unexpectedly and only after hours of subsequent play without such shots. Yet, the same performance could easily be improved by specially designed activities. For example, a tennis player could hit many consecutive back-hand volleys under the supervision of a tennis coach, who could create back-hand volleys of suitable difficulty. When first learning to control a basic stroke, the trainee benefits from simple shots, at least initially. Later, the trainer will challenge the tennis player with less predictable and more difficult shots that are embedded in a representative game context. Optimal training involves exactly this design and presentation of situations that challenge the trainee at just the right level of difficulty. In order to succeed with challenging shots, the trainees have to be able to focus with full concentration so they can identify sources of failures and correct them during repetitions of hitting similar shots. "Deliberate practice" is the term that Anders Ericsson and colleagues (Ericsson, Krampe, & Tesch-Römer, 1993) have coined for such training activities that are designed by a teacher solely for the purpose of improving an individual's performance. When a trainee engages in practice to improve aspects of their game by themselves without the direct help of a coach Anders Ericsson and Robert Pool (2016) used the term purposeful practice to distinguish those activities from deliberate practice. They also introduced the term naïve practice to refer to participation in regular activities in the domain, such as playing soccer games or tennis matches against friends or merely performing the regular work activities in a domain of professional expertise. Contrary to what one might think, active participants in domains, such as tennis, golf and many professions, rarely engage in deliberate practice. Although they recognize that engaging in this type of training would improve their performance, they also find it so much more effortful and less enjoyable than regular recreation or work – that its costs outweigh its benefits. Engaging in a domain activity is usually motivated by its inherent enjoyment (play) or external rewards (work). Yet these activities lack essential pre-requisites for efficient improvement which deliberate practice offers, including training goals, feedback and opportunities for gradual improvement through repetition. Active engagement in a domain does not invariably lead to improvement of performance once some initial acceptable level has been attained.

It is well established that mere engagement in activities of the domain is necessary but by itself not sufficient for attainment of very high (expert) levels of performance. In many domains, promising individuals are supervised by a teacher who instructs them and designs their practice from a very young age. Benjamin Bloom and his colleagues (Bloom, 1985) found out through interviews with international level performers in mathematics, bio-chemistry, music, sculpture, swimming and tennis that they had studied with excellent (master) teachers. In fact, many of these performers or their families had even relocated to be close to a desired teacher or an excellent training environment. Virtually all of them had studied with teachers who either were international level experts themselves or had successfully trained students to reach that level.

Why is it nearly impossible for individuals to guide themselves to expert levels of performance without the help of teachers? Moreover, why does the level of excellence of teachers appear to be so important? Whereas the general cognitive development in children is surprisingly invariant across very different environments and cultures, the development of expertise in domains of expertise, such as music, sports and science, shows large differences across varying cultures and historical times. One of the primary reasons is that domains of expertise have over time extracted and accumulated a body of organized experience in the form of knowledge and produced artifacts. This body of externalized, written-down or otherwise documented, and codified experience can be shared with subsequent generations through teachers, books, and other media. It is no longer necessary for each individual to re-discover pieces of knowledge and methods for doing things, and individuals are thereby able not simply to match but to surpass the level attained by pioneering predecessors. In the 13th century, for example, Roger Bacon argued that it would be impossible to master mathematics in less than 30 to 40 years by the contemporary method of learning through self-study; Bacon was talking about a material roughly equivalent to the mathematics which is today taught in well-organized and accessible form in high schools everywhere.

The necessary role of teachers in mastering any of the arts and sciences becomes apparent when one considers that the accumulation of knowledge and achievements is based on specific shared concepts, symbolic systems, technology (in a very broad sense, e.g., instruments, equipment, materials), and theories with efficiently organized knowledge. Generally, we take the increases in level of expert performance over historical time in science and sports for granted. Given the large changes in technology in these domains, it is difficult to make inferences about the actual changes in skill. Yet, in domains with less changing

technology such as music performance on the piano or the violin, today's performers readily master music that was, by the best musicians in the 18th and 19th centuries, initially considered unplayable. Similarly, in many sports with minimal equipment, such as running or swimming, the highest level of performance attained early in this century is now common place and matched by serious amateurs.

In all major domains there has also been an accumulation of effective methods for teaching the growing body of knowledge and skills. By going through the sequences of training tasks that teachers and coaches have developed over the last centuries, students eventually perform more complex tasks than they thought they would be able to master. Unlike the beginners themselves, the teacher can foresee future skill demands. They know with what method and to what degree of mastery the simpler tasks have to be learned to serve as a solid foundation for more complex future skills. If the simpler skills are not acquired properly, the student might have to completely relearn the fundamental skills. The core assumption of deliberate practice is that expert performance is acquired gradually and that effective improvement of students' performance depends on the teachers' ability to isolate a sequence of simple training tasks that the student can successively master by repetition with feedback and instruction. As mentioned earlier, the individual training tasks have to be difficult enough to lie slightly outside the students' current range of skills, so that the students concentrate on critical aspects and gradually refine their performance through repetition in response to feedback. This requirement of focused attention to individual task components differentiates deliberate practice from both mindless drill and playful engagement. In the best of cases these latter two activities would strengthen the current structure of the performance but not modify it to permit reaching a higher level of mastery.

In many domains, promising children start training with teachers at very young ages. Because of the requirement of sustained concentration, the duration of training is initially quite short – typically no more than around 15 to 20 minutes per day. This leaves enough time for many other more playful but still domain-related activities. Many parents supervise their children's practice by helping them to concentrate during practice, by establishing regular practice patterns, and by encouraging them. With increasing age, domain-related activities, especially deliberate practice, occupy more and more room in the daily lives of future expert performers; by the end of adolescence the commitment to the domain is essentially full time.

Using diaries and other methods to study how expert musicians spent their daily lives, Ericsson and colleagues demonstrated the importance of deliberate practice for attaining expert performance. They investigated three groups of experts differing in their level of music performance. Although all experts from the three groups spent about the same overall amount of time with music-related activities each day, the better musicians spent more time in deliberate practice; the top two groups spent around 4 hours every day, including weekends, in solitary practice. Based on retrospective estimates of past practice times, the researchers calculated the number of hours of deliberate practice accumulated by the different groups of musicians (see Fig. 2). By age 20, the best musicians had spent on the average over 10,000 hours of solitary practice, which was around 2500 and 5000 hours more than the two less accomplished groups of expert musicians; and 8000 hours more than typical amateur pianists of the same age. A number of studies in chess, sports and music have confirmed the relationship between performance and amount/quality of deliberate practice. The broad range of known evidence suggests that most of the individual differences in giftedness or talent can be attributed to differences in practice history, rather than innate differences in talent, especially among children.

Some critics of the benefits of practice have unfortunately viewed deliberate practice as merely drilling with the goal of attaining rapid and effortless automaticity. However, the next section will show that developing expert performance results in acquisition of

Figure 2 Estimated amount of time for solitary practice as a function of age for the middle-aged professional violinists (*triangles*), the best expert violinists (*squares*), the good expert violinists (*empty circles*), the least accomplished expert violinists (*filled circles*) and amateur pianists (*diamonds*). From "The role of deliberate practice in the acquisition of expert performance," by K. A. Ericsson, R. Th. Krampe and C. Tesch-Römer, 1993, *Psychological Review*, 100(3), p. 379 and p. 384. Copyright 1993 by American Psychological Association. Adapted with permission.

complex mental mechanisms. Experts rely on these mechanisms to evaluate, reason, and improve planning, and also to continue learning without a teacher, essentially becoming their own teachers.

The Structure of Expert Performance

The development of performance of most active individuals in a particular domain is often arrested once an acceptable level of performance has been reached. These individuals want to achieve effortless performance, similar to how they mastered most everyday activities, such as driving a car or typing. In contrast, aspiring expert performers want to improve important aspects of their performance with deliberate practice and continue to do so for years and decades. The key challenge for these performers is thus to avoid a stagnation in their development and instead acquire mental mechanisms that can support continued learning and improvement. What these cognitive mechanisms are and how they mediate performance will be explained in the next two sections.

Cognitive Mechanisms That Mediate Superior Performance

By giving experts representative tasks that capture the essence of the expertise in their domains, it is possible to reproduce their superior performance in the laboratory (Ericsson & Lehmann, 1996). Fig. 3 gives some examples of tasks for which experts' performance in the laboratory would correspond closely to real-life measures of performance used in their domain. In laboratory experiments researchers can instruct the experts to think aloud while they perform a certain task or give a retrospective report immediately afterwards. A recent review by Anders Ericsson shows that in a wide range of domains experts' think-aloud protocols reveal precisely how their superior performance is mediated by preparation, planning, reasoning and evaluation. The first example in Fig. 3 illustrates de Groot's procedure where different chess players are asked to select the best move to a set of unfamiliar positions from published games of elite players. By presenting medical doctors with descriptions of a particular patient's symptoms and asking for a diagnosis, one can similarly study medical doctors' expertise. In both above examples the correct solutions are known to the researcher: We know what move the best chess computer programs would make (these programs are far better than any human player), and we know what disease the patient was eventually diagnosed to have, sometimes from autopsies or advanced tests. The second example in Fig. 3 illustrates how to reproduce superior typing performance in a controlled situation by instructing every typist to copy the same material. The final example shows how musicians can be asked to give multiple renditions of the same piece of music. All three types of expert performance are mediated by different types of acquired cognitive mechanisms. The mechanisms mediating chess and medical diagnosis have many similarities, but the mechanisms underlying expert typing and performing music differ and will be considered separately.

When highly skilled chess players select the best move for an unfamiliar position, they rapidly identify potential moves which are retrieved from among the many moves they have previously stored in memory. To select the best move the players then examine the retrieved moves by mentally planning out their consequences. During this evaluation even world-class players can discover better moves than those they retrieved at first glance. Although chess experts can retrieve acceptable moves seconds after being confronted with a new chess position, their move selection is further improved by planning, reasoning and evaluation. This indicates that performance of experts is not completely automated but remains controlled by increasingly complex processes. The ability to anticipate what consequences a particular chess move would have after several move exchanges increases slowly as a function of chess skill. Chess

Domain	Presented Information	Task
Chess		Select the best chess move for this position
Typing		Type as much of the presented text as possible within one minute
Music		Play the same piece of music twice in same manner

Figure 3 Three examples of laboratory tasks that capture the consistently superior performance of domain experts in chess, typing and music.

masters have perfected this type of planning to a point where they are able to play chess blindfolded, that is without seeing a chessboard, and relying entirely on their mental image of the chess positions. Experts from other domains reveal similar characteristics.

The processes that mediate the performance of medical experts allow them to extract the relevant information about a patient better than less accomplished doctors. Also, they can entertain and reason through alternative diagnoses so they can identify the best-fitting diagnosis by a process of successive elimination. Thus, at higher levels of performance, individuals have acquired the ability to mentally represent relevant information. This information is made accessible in a fashion suitable for supporting more extensive and flexible reasoning about an encountered task or situation. In most domains, better performers have acquired complex memory skills that allow them to rapidly encode and store relevant information during representative tasks. However, as mentioned earlier, their superior memory skills are developed to encode information related only to executing superior performance in their domain of expertise.

Even the rapid typing speed of expert typists appears to depend on acquired representations rather than mere superior general speed of their nervous system or finger movements. High-speed films of typing show that expert typists look ahead in the text beyond the words that they are currently typing and move their fingers in position for anticipating upcoming keystrokes. In fact, the best predictor of individuals' typing speed is how far they look ahead. Accordingly, in experiments where typists were restricted from looking ahead in the text, their typing speed was dramatically reduced. During the mastery of typewriting the expert typist has acquired the skill to look ahead in the text in order to prepare future keystrokes. Similarly, the rapid reaction times of athletes such as hockey goalies, baseball hitters and tennis players, have also been found to reflect the ability to anticipate future events.

In many instances, the relevant information that performers extract and encode changes as a function of attained level of performance. For example, the primary reason that expert tennis players can so rapidly intercept and return a fast serve is the following: rather than looking at the actual trajectory of the ball once it is hit, they anticipate the ball's path from the preparatory body movements of the server; they are even able to make rough predictions before the server's racquet makes contact with the ball. Hence, the resulting shorter reaction times of experts (as compared to less accomplished individuals) in a domain of expertise are not explained by an innate basic speed advantage but by superior anticipation, preparation, and improved perceptual skills.

Finally, expert musicians are well known for their ability to control their expressive performance of a given piece of music to convey a different musical interpretation. This ability would be difficult to study if the performance changed every time the musicians performed. Laboratory studies have shown however, that if expert musicians are instructed to play the same piece several times in as similar a manner as possible, they are able to reproduce their own performance very accurately from one rendition to the next. Expert artists have a high level of control along with a precise image of their own performance, allowing them to reproduce or vary a performance at their will or to satisfy external requests or their own aesthetic decisions.

In sum, expert performance is not simply characterized by reduced cognitive processing and automatization. In fact, in order to reason about, anticipate, and plan alternative future actions, experts increase the control over their performance and their ability to internally represent it. This control is essential for experts in order to select appropriate behavior. In the case of athletes this could mean capitalizing on an opponent's weakness or taking into account the weather conditions; for the performing artists it may imply adapting to unfavorable room acoustics or synchronizing with other members of the ensemble. Imagine competitive domains, where newly discovered techniques or knowledge constantly change the *status quo* of a domain, or where each tournament takes place with different opponents and in unfamiliar locals. If experts were not able to adapt rapidly to those conditions, the emerging weak points would be exploited by others. Thus, in order to maintain high levels of performance despite any changes in the environment, experts need to possess a flexible, generalizable skill.

Cognitive Mechanisms That Mediate Learning

Attaining expert performance in a domain appears to depend on the acquisition of mental representations that permit control and monitoring of the gradual improvements. Only when the expert performers themselves can image and plan their desired performance, and monitor and evaluate their own ongoing performance, are they able to become independent of their teachers and coaches, and reach their highest levels by engaging in purposeful practice. Developmental studies show that the improvement in representations goes hand in hand with increases in observable performance. Thus, a similar development of representations appears to be the key mechanism that prepares students for adult independence.

Bloom (1985) showed that the training of expert performers can be roughly broken down into three phases illustrated in Fig. 4. After a brief period of playful engagement in a domain (Phase I) some children are introduced to systematic practice in the domain (Phase II). The teachers will present the beginners with simple training tasks and often explicitly guide their students to focus their attention on critical aspects and to make specific changes and corrections. Parents or teachers normally help the children, at least initially, to monitor their performance and to give feedback on how well the training goal was attained. As the complexity of the acquired level of performance increases, so does the complexity of the practice tasks and goals. With further increases in performance, some individuals reach a point where they decide to commit full-time to the domain and make it their professional career (Phase III). Along with the improvement of observable performance, students acquire improved representations to image the desired performance and to monitor their own performance, and they learn how to reduce discrepancies between the two. For example, musicians must be able to internally represent many different aspects of their music performance, such as how a given music performance should sound to an audience, and how to play their instruments to achieve this goal. In this context, it does not matter whether the musician is in the practice room or performing in public. It seems unlikely that a musician who fails to acquire any of these representations would be able to perfect their music performance through solitary practice.

Figure 4 Three phases of acquisition of expert performance, followed by a qualitatively different fourth phase when experts attempt to go beyond the available knowledge in the domain in order to make a creative contribution. From “Can we create gifted people?” by K. A. Ericsson, R. Th. Krampe, and S. Heizmann in *The origins and development of high ability* (pp. 222–249), 1993, Chichester, UK; Wiley. Copyright 1993 by CIBA Foundation. Adapted with permission.

When the expert performers have finally assimilated most of the available knowledge and skills in the domain, they start their professional career. During this fourth phase that Ericsson and colleagues added to Bloom’s three phases, the primary goal is to make a personal creative contribution to the domain. By making those major innovations that permanently change the conception of performance or training in the domain, some expert performers will be able to reach a new level of achievement in the domain.

With the help of their highly developed representations skilled performers can eventually design and monitor their own training to further improve their performance. Studying and analyzing performances and achievements of masters in the field is one important way of doing this. For example, expert chess players collect books and magazines with published games of chess masters. Similar to the laboratory task mentioned earlier, they play through those games move by move and try to predict the next best move the master could have chosen. Any inconsistency between their own prediction and the chess master’s actual move would imply that they overlooked some aspect of the configuration during their planning and evaluation. According to Neil Charness and collaborators (Charness, Tuffiash, Krampe, Reingold, & Vasyukova, 2005), serious chess players spend up to 4 h every day with this type of solitary study (purposeful practice). In general, this form of self-study is theoretically interesting because attempting to copy the model behavior of established masters allows the performers to gradually refine their own independent representations and expand the body of knowledge and skills in a domain beyond what has been accumulated over decades and centuries.

Expert Performance and Creative Achievements

Within the framework of expert performance, the first three phases of training leads to increases in the quality and generality of the aspiring experts’ performance by learning from teachers and experts, thus benefiting from already codified knowledge and insights about performance and deliberate practice in a given domain. During Phase IV a small number experts go beyond and thus redefine the current boundaries of a domain of expertise and generate creative innovations. This view contrasts sharply with the popular view that creativity is reflected in children’s spontaneous behavior and that education and extensive training tend to constrain and suppress creativity rather than enable it. In fact, the expert performance perspective maintains that without training students do not acquire the necessary representations for imaging and generating their products and achievements. To even have a chance to make a genuinely new innovation it is necessary to have assimilated the previously accumulated knowledge and be familiar with earlier, similar achievements. Only extended education will allow an individual to recognize a purposefully generated innovation as being uniquely new and different from prior achievements by others.

As far as is known, the empirical evidence on creative achievement shows that individuals have not been able to make major creative contributions to a domain unless they had mastered the relevant knowledge and skills during a long preparatory period of study and training. Even prodigious children seem to need extensive experience and training, and their creative achievements do not always compare well when judged by adult standards. Not even in the cases of revolutionary innovations by individuals

such as Einstein and Picasso, did [Howard Gardner \(1993\)](#) find that the key creative innovations were generated until the creative individuals had completed their study and mastery of the existing knowledge and techniques (See Evolving Systems Approach).

Furthermore, careful analyses of extraordinarily gifted children have shown that the trajectory of development they follow is similar to that of normal children engaged in the same domains. The difference appears to be that gifted children progress through the stages faster than less gifted children, attaining higher levels of proficiency at younger ages. Detailed analysis of the mechanisms mediating the very high level of performance of children in tennis and chess suggests the same types of acquired mechanisms as those of adults with comparable level of performance. These findings do not support claims of qualitatively different mechanisms in talented children. In music, and also in other artistic domains, researchers have found that the higher achieving children tended to practice more on a daily basis than the lower achievers and typically have more accomplished teachers. This higher involvement along with motivational differences, for which Ellen Winner has argued convincingly, may account for the faster progress of some children over others.

In conclusion, the training of expert performers should not stifle creativity but rather provide the tools to empower the experts to be more successful and effective in their daily work and their search for innovative ideas, especially those few that go beyond what is currently known and done. Equipped with the rich knowledge of other experts' creative achievements through extensive education, the artists, scientists, athletes, or other expert performers can explore possibilities, and perhaps generate major innovations, thus making lasting contributions to their domain ([Ericsson, Hoffman, Kozbelt, & Williams, 2018](#)).

Glossary

Aesthetic responses are the physical responses that arise in the presence of a creative act or work of art.

Art as Medicine is a healing process in which the person meditates and engages with the images, tells stories about the artwork, dialogues with the art, and dramatizes insights through bodily movements.

Authentic Movement is often used as an improvisational physical movement practice to access internal body sensations and feelings. Unconscious impulses that emerge through movement are expressed in the moment.

Creativity includes four main components process, person, product, and press of the environment. Creativity may lead to a product, idea, object, or behavior that is both original and meaningful to others. Expressive arts can accentuate the creative process by offering an encounter or intense engagement with one's environment and life experience.

Creative Arts Therapists specialize in an art modality such as dance/movement therapy, drama therapy, music therapy, poetry therapy, or psychodrama. Each of these areas has its own set of professional standards and qualifications. The National Coalition of Creative Arts Therapies Associations was founded in 1979 and represents over 15,000 individual members of six creative arts therapies associations nationwide.

Everyday Creativity is a process and a way of life that consists of the capacity to experience the world in original and meaningful ways. This includes a wide variety of human endeavors, including work, family life, community involvement, extracurricular activities, and processes that support life-long learning.

Expressive Arts is a field within creative arts and psychology. Practitioners combine and integrate visual arts, movement, drama, music, writing and other creative processes to foster growth and transformation with individuals and groups for the purpose of providing clarity, creativity, healing, and illumination.

Expressive Arts Therapy is an interdisciplinary, integrative process using psychotherapy, creative arts and forms of creative expression for therapeutic healing.

Expressive Writing when combined with intermodal expressive arts, is a process of freeform writing about emotions and experiences. It supports the integration of insights that arise from using other expressive art modalities.

Imagination is the forming of new ideas and the capacity to be creative. The modalities of imagination include movement, words, visual images, actions, and sounds and rhythms.

Intermodal Expressive Therapy is a specialized and focused psychotherapeutic discipline using verbal and nonverbal communication grounded in the imaginative traditions of the arts. The user moves from one art modality to another within the process of play.

Person-Centered Therapy provides psychological safety for a person to access vast inner resources that encourage understanding and self-directed behavior. The three conditions that foster a person-centered relationship are unconditional positive regard, accurate empathy, and congruence, or the consistency of inner feeling and outer expression.

Person-Centered Expressive Arts is the combination of unconditional positive regard, empathy, and congruence with art, movement, sounding and writing for self-exploration and integration in a safe and supportive environment.

Registered Expressive Arts Therapists (REAT) use the expressive arts in therapy, social work and counseling and may work in hospitals, private practice, or residential facilities for individuals, or for global organizations.

Registered Expressive Arts Consultant Educators (REACE) use the expressive arts in teaching, coaching and consulting and across a wide spectrum of disciplines such as education, coaching, workshops, healthcare, hospice, peace building, organization development, cultural change, non-profit work, spiritual development, and conflict resolution.

Relational Creativity involves bringing authenticity, empathy, presence, originality and personal qualities that permit openness and mutuality. Relational creativity includes ways of manifesting interpersonal, intrapersonal and spiritual potential for oneself and others.

Self-actualizing Creativity as described by Abraham Maslow, fulfills one's humanness and is the ultimate expression of a person attuned to and living the Being Values of truth, justice, and beauty. Some of the aspects of everyday creativity contributing to self-actualization are bringing to a situation one's unique perspective and way of being.

Sounding includes chanting, drumming, music, and vocalization for the purposes of emotional expression, healing, and integration.

Introduction

Expressive arts is an interdisciplinary and arts-based approach for personal growth and social transformation that can be used in counseling, coaching, consulting, education, psychotherapy, and social transformation. Expressive arts is a relatively new field, occupying the ground between creative arts and psychology. Practitioners use the visual arts, movement, drama, music, writing and other creative processes with their clients to foster healing, personal growth, and social change.

Engaging with the arts represents a reclaiming of ancient creative rituals and traditions used to celebrate nature and honor the cycles of life. Art, dance, drumming, music, play, poetry, singing and storytelling have been used for centuries, if not millennia, as ways to express humanity's deepest spirit, honor the milestones of human life and the seasons, and reasons for being alive.

In the early modern era (1930–40) of using creative arts for healing, practitioners focused on using a single creative art for therapy, developing disciplines such as art therapy, music therapy, dance-movement therapy and drama therapy. However, these typically involved some verbal interaction and interpretation. Some patients were unable to participate in talk therapy including individuals with autism, cerebral palsy, speech impairment, or impairment from strokes. New methods were needed.

Unlike healers who specialize in one art form, expressive arts practitioners mix the visual arts, movement, drama, music, writing and other creative processes. Expressive arts combine forms of creative expression for many purposes: self-awareness, therapeutic healing, everyday creativity, understanding the psyche/soul, individual and collective growth, community building, and social transformation.

Pioneers in Expressive Arts

Some of the pioneers in expressive arts are Paolo Knill, Shaun McNiff, Arthur Robbins, and Natalie Rogers. Paolo Knill was trained as a physicist, musician, and later as a psychologist. He was an author, a performance artist, and co-founder of the European Graduate School, based in Switzerland and Malta. Two of his major contributions to the field included the philosophy of taking the *whole being* into the learning process and using the performing arts in his work as a psychologist. Knill developed "intermodal expressive therapy," which engages imaginative realms through the process of play while the person moves from one art modality to another. For example, the experiencer would share a painting and poem in a small group and then add movement and sound.

Intermodal theory proposes that each art form contains the seeds of other art forms, such that a drawing may inspire a person to dance the emotions that were expressed in the drawing. Intermodal expressive therapy uses both verbal and non-verbal communication between the client, the art process, and the therapist. When the transition occurs from one art form to another, the client's experience can be amplified, clarified, and understood in new ways. An example of an intermodal transfer is sharing a painting and poem in a small group before adding movement and sound to enhance the imagery (Knill et al., 2003, 2005).

Shaun McNiff is a painter and teacher who established one of the first intermodal expressive arts training graduate programs, at Lesley University in Cambridge, Massachusetts. McNiff, who began as an art therapist, teaches about the interconnectedness of the healing power of the arts, art as medicine, the creative process, and imagination. After an image is created, a participant might paint a picture, pause to have a written or oral dialogue with it, then return to working on the painting. This process peels back layers of defenses or blocks to understanding. Emotional responses and messages from the body are then incorporated into the painting.

McNiff emphasized being aware in the *present moment* while engaging in the creative process, as opposed to breaking the art process into a specified sequence of moving from one art modality to the next. He rejected an overreliance on rationalism and psychopharmacology. Building on Jung's concept of active imagination, McNiff recommended dialoguing with images through painting, movement, and storytelling as a way to activate one's creative energy. He has been a prolific author on the topics of art-based research, art as the source of healing, and the creative imagination (McNiff, 1992, 2015).

Arthur Robbins is a psychologist, depth-oriented therapist, sculptor, teacher, author and co-founder of the Pratt Institute Creative Arts Therapy program in New York. Robbins used the arts to explore and define concepts such as play, creativity, holding and

containment, transference and counter-transference. He referred to expressive arts therapy as the cohesion of three different levels of consciousness: the mind, body and spirit.

Although Robbins's framework was originally based on art therapy, he argued against the limitations of using the single modality of visual art. He asserted that there was strength in using a creative arts approach with multiple art forms including dance/movement, puppetry and music. He recommended that even though an art therapist may cultivate a specialization in one art form, such as drawing, the therapeutic training should stretch into multiple areas of creative expression and focus on the creative process. He advised that the creative process should be customized for the client and not be limited to one therapeutic model. Robbins believed that "every art therapist must possess and develop the soul of and sensitivity of an artist" (Robbins, 1994, p. xiii).

Natalie Rogers was a psychologist, artist, teacher and founder of the Person-Centered Expressive Therapy Institute in Santa Rosa, California. She began integrating the arts in her private practice with children and adults and entered the field of expressive arts through her work in play therapy.

After working as a psychotherapist for twelve years, Rogers began working with her father Carl Rogers in 1974 on a series of 10-day person-centered workshops. She quickly found that sitting through long verbal sessions was difficult for her and other participants, and that additional outlets were needed to work with the pain and anger that can emerge in group therapy. Natalie invited smaller groups of workshop participants to use experiential processes with art, movement and psychodrama to relieve physical tension, cultivate somatic awareness, and to explore deeply held emotions. This experimentation was the beginning of her life-long contribution: integrating the person-centered philosophy with the multi-modal expressive arts process she named the *Creative Connection* (Goslin-Jones and Herron, 2016a).

To design a *Creative Connection*, Natalie Rogers recommended using a variety of art materials and creative experiences in a multi-modal process with individuals or groups (Rogers, 1993, 2011). Person-centered expressive arts guidelines are offered to participants at the beginning of each session to foster a safe and supportive environment. Trust is established by extending guidelines such as 1) Everything is an invitation, 2) Feelings are a source of creative expression to be channeled into art-making, 3) There is no right or wrong way to make art, 4) Be aware of your feelings and body and take care of yourself, 5) Expressive arts stirs up feelings; crying, sounding and expressing emotions can be extremely helpful (Goslin-Jones and Herron, 2016a; Rogers, 1993). The person-centered expressive arts approach is a flexible structure that invites participants to make personal choices using a variety of modalities such as art, movement, sounding and writing for the purpose of accessing inner resources for greater self-awareness.

Expressive Arts Process

There are numerous ways for an expressive arts session to be offered. The book *Integrating the Expressive Arts into Counseling Practice* presented a collection of field-tested expressive arts interventions used by counselors and educators (Degges-White and Davis, 2018). Various counseling theories were discussed and relevant expressive arts interventions described, including goals, population, materials, and instructions. The authors explained how using intermodal expressive arts to develop a tangible product (ex. collage, image, sculpture, story, painting or dance) may lead to greater self-awareness.

Applications With Individuals

An individual expressive arts session might start with a brief 5-min mindfulness meditation. Then the participant may be invited by the EA professional to move or gesture in spontaneous ways that convey feelings or physical sensations. When the movement feels complete, the facilitator invites the participant to express his or her feelings using art supplies. This activity can be as simple as using the non-dominant hand with crayons, or it may be making a collage, clay sculpture, or sock puppet, or finding objects in nature that represent feelings, desires or challenges. Next, a writing prompt may be offered, such as "I am, I feel, I need," to encourage the participant to capture the experience in words. Finally, there is an opportunity to share the creative process orally with the facilitator.

A therapist who works with mentally ill adults living in transitional housing and the homeless gave the following account:

Peter; a 30-year-old, homeless man with whom I had developed a tenuous relationship, seeing him only about once every six weeks, over a period of a year. One day I found Peter sitting behind a building in a drainage ditch where a group of young homeless men hung out during the day. On this day Peter was alone and appeared to be very depressed. I asked permission to sit beside Peter and he consented. After sitting quietly for several minutes, Peter replied that he had recently found out his father had died. He was feeling tormented that he had been unable to be by his father's side as he died or attend his funeral.

I asked Peter if he would like to write or draw a letter in chalk, reassuring him I would help him sweep the drawing away so no one would see it, if he wished when he was finished. Peter asked if he could create a tribute to his father, so I found a deserted parking lot and provided Peter with a bucket of chalk. He created a very large tribute taking up over three parking spaces. Peter drew his father and the items he felt were important in their relationship including a bible, several guns, military images, and his family home. The drawing of his father was over seven feet tall, the guns were six feet in length, and all other items were oversized, except for his family.

Would this creative intervention make a difference in this man's life? The therapist said that the session brought about:

a major turning point in the therapeutic relationship. Peter demonstrated this remarkable turnaround by his willingness to meet with me more often, take his medication regularly, and by successfully moving into transitional housing. Three years later, Peter was married and is still married after 5 years (Goslin-Jones and Herron, 2016b, p. 99).

Applications in Group Settings

Expressive arts are also used in a group format for education/training/self-awareness and community development. The group might consist of a class of students, a group of co-workers, or a community agency. Various art materials and experiences are offered. The intermodal use of movement, art-making, sounding and writing provides a way to work through conflicts and to discover creative solutions. When expressive arts are used with a group, the session may range from 90 minutes to week-long workshops. This is an example of an individual's experience in a group setting:

While I was in the expressive arts experience, we used art-making to create a portrait of our body. The session was called "Wisdom of the Body." We later moved and danced to the portrait and then reflected on the experience. I was able to process a lot of information about my relinquishment at birth and being adopted, and my adopted parents' divorce when I was 10. I processed layers I had no clue were there and because of that I felt like I could fly at the end of that course.

Goslin-Jones (2010), p. 168.

Those interested in reading more vignettes should consult *Creative Connections with Groups* (Rogers, 2011), which included articles from 26 expressive arts practitioners. The practitioners work with children, adolescents, adults and elders on issues such as addiction, anger, Alzheimer's/dementia, cancer, cultural bridging, developmental disabilities, eating disorders, empowerment/self-esteem, grief, refugee children, stuttering, spirituality, professional development for therapists, teacher education, victims of crime, mindfulness for veterans, and unleashing creativity in the workplace.

An expressive arts participant may find the practice so worthwhile that he or she continues it after the session ends. Another participant reported,

Expressive arts have probably been most helpful on a day-to-day basis. If I feel angry or unhappy, I observe my feelings and then take my journal and scribble, draw, or create a collage. It may be just 10 minutes. It is a way of defusing tension. It is a way of getting back in touch with myself and noticing if something doesn't feel right in my body.

Goslin-Jones (2010), p. 167.

Expressive Arts and Social Change

The book *Art in Action: Expressive Arts Therapy and Social Change* (Levine and Levine, 2011) presented a collection of expressive arts interventions used to foster social change. Case studies included a clinic for displaced Iraqis in Jordan, Bosnian refugees in Slovenia, and HIV-positive women in prison. Collaborative poetry writing, dance, and drama were used with survivors of war to address the hardships they experienced and to help them find new ways of working together. Outdoor spaces that had been destroyed were reclaimed and recreated into art spaces and community galleries. Expressive arts were employed by Natalie Rogers (1993) to build bridges across cultures in Europe, Mexico, Japan, Philippines, South America and the former Soviet Union.

Research

Prior to 1980, there was more extensive research in art therapy, but minimal research in the use of intermodal expressive arts. During the past 10 years, research on expressive arts has increased on a wide variety of topics, as indicated in Table 1. Such research has been

Table 1 Expressive arts research and professional publications

Years	Dissertations (ProQuest)	Master's theses	Peer rev journal articles (web of science)	Peer rev journal articles (PsycINFO)	Books (WorldCat)
1960–69	2	0	0	0	13
1970–79	3	0	4	2	76
1980–89	21	1	10	13	88
1990–99	32	15	14	32	224
2000–09	57	23	30	60	249
2010–18	103	52	76	149	421

published in doctoral dissertations, master's thesis research, peer-reviewed journals, and many books. As demonstrated in [Table 1](#), professional publications in the field have vastly expanded in number since then. The following data was collected by the present author using the search terms, "expressive arts or expressive art".

Expressive arts are used for community-based action, coaching, conflict-resolution, decision-making, everyday creativity, grief work, innovation, personal growth/empowerment, psychotherapy, stress reduction, product development, self-actualizing creativity, team-building, and workplace transformation.

As is true in many fields, there is no single archive that includes all research published on expressive arts. Additional expressive arts research may be available in other areas such as anthropology, education, and sociology. Combining art-making, music, movement, and writing with other creative processes is a powerful way to support health and well-being. The arts have been applied in mental health, education, the workplace, and the community. A major advantage is that a person needs no artistic experience to use the arts, because it is the *process* of art making and not the product that releases blocked emotional and physical energy. The client is offered creative processes to develop his or her own innate creativity and this facilitates new forms of self-expression. Words can be limiting, and expressive arts invites a multi-layered communication using art, movement, sound, and writing. This creative process also includes reflection and improvisational skills and is a way to be present with oneself and with other group members to access and re-ignite creativity.

Expressive arts increase self-awareness that facilitates physical, emotional and spiritual well-being ([Goslin-Jones and Richards, 2018](#); [McNiff, 1992](#); [Rogers, 1993, 2011](#)). It can also serve as a catalyst for increasing emotional intelligence or relational creativity. Relational creativity involves bringing authenticity, empathy and presence to oneself and to others and, when effective, can deepen relationships and connection. Expressive arts can be a bridge or pathway to access one's intuition and creative capacity.

For example, a research participant named Carmen said she accessed preverbal knowledge by engaging her body in movement, activating her senses with art-making, and using musical expression.

You end up discovering that you know things you did not know that you knew, because they are preverbal. After you participate in an expressive arts experience, you complete the process by writing down your words and stories and then you share it verbally. You have brought up wisdom from a deep place where it was preverbal; you didn't know that you knew it. Suddenly there it is and now you can talk about it.

[Goslin-Jones \(2010\)](#), p. 92.

Expressive arts can also be helpful to those with limited awareness. Sandy was 78, diagnosed with dementia and depression, residing in an eldercare residence. Sandy was offered expressive arts to enhance her social interaction and support her emotional well-being ([Goslin-Jones and Herron, 2016b](#), p. 95).

After two individual sessions the therapist introduced music, movement, and art. While sitting in her chair, Sandy and the therapist would both raise their arms together in the air, rotate their wrists in circles, and sway their arms to Sandy's favorite music.

After these movement exercises, the therapist would invite Sandy to choose art supplies such as brightly colored paper, cut out shapes, magazine images, pastel chalks or crayons, and proceed to make art. In the first art session, Sandy had difficulty choosing any color of paper, shapes or images to make her collage. The therapist would slowly go through the different colors, asking if she liked red, blue, green, yellow, until Sandy pointed to the one she liked and that color paper was used for a canvas.

As the sessions progressed, Sandy was able to quickly choose the supplies she wanted. She glued her own images onto the paper and learned how to enhance her collage with chalk pastels and crayons without assistance. As the sessions progressed, Sandy's mood became more positive and she looked forward to each session. After 4 sessions, Sandy began sharing her artwork with other residents, asking how they liked her art. Other residents liked her art and began to join Sandy's expressive arts sessions.

Research studies indicated that expressive arts processes helped participants develop abilities in artistic expression, communication skills, compassion, conflict resolution, decision-making, empathy, everyday creativity, intuition, listening, mindfulness, problem-solving, relational creativity and greater wholeness ([Goslin-Jones, 2010](#); [Goslin-Jones and Herron, 2016a,b](#); [Goslin-Jones and Richards, 2018](#)).

Risks and Challenges in Using Expressive Arts

One of the primary requirements for participants in an EA experience is a safe environment free from criticism or interruption. Some community environments or workplaces may not be conducive to engaging in free forms of expression or offer a supportive environment. Art-making and expressive arts processes can easily stir up emotions, and in many organizations feelings are not openly

expressed. In group situations, some participants may dominate, others may feel inhibited, while yet other participants withdraw because of creative blocks.

The sensitivity, self-awareness, and skill set of the facilitator are critical. The facilitator needs to provide healthy boundaries by establishing and modeling respect, personal responsibility, non-judgement, empathy, and trust. If an expressive arts experience triggers highly emotional memories that have been buried, the facilitator may need to moderate the pace and offer multiple ways to process strong emotions, especially in group or workplace situations.

The candor and authenticity that can emerge from expressive arts may feel threatening to friends and family members. Some people dismiss expressive arts and feel that it is a waste of time, because it can feel playful and it is hard to measure results. Finally, it is challenging for some students and clients to sustain an expressive arts practice after the formal education, therapy, or group experience ends. However, even though there are some risks to using the arts, the research participants who used expressive arts in one study stated that these benefits greatly outweighed the risks (Goslin-Jones, 2010). As the field continues to grow, further research into impacts on other populations and circumstances will be important.

Development of the Field

During the 1980's and 1990's, the field of expressive arts expanded as educational programs emerged and therapists introduced the use of multi-modal arts into their work. After experiencing challenges with the for-profit *National Expressive Therapy Association* (NETA), several professionals in the field decided to create an alternative, non-profit organization that was membership-based and led by volunteers. The co-founders, Jack Weller, Anin Utigaard, Stephen Levine, and Phillip Speiser, named the new non-profit the *International Expressive Arts Therapy Association* (IEATA®). It was a significant change to include the word *arts* in the title and to make the framework for the non-profit organization interdisciplinary, using the arts, creative process, and psychology as integral aspects of the professional work and philosophy. The expressive arts field expanded to include therapists, educators, and consultants.

IEATA was founded in 1994 and hosts international conferences, provides professional guidelines, ethical standards, and a professional network to bring expressive arts into the world for “growth, healing, communication, and collaborative learning” (<https://www.ieata.org/>).

It was important to the founders and members that using different art modalities in an intermodal process (visual art, drama music, movement, poetry, and writing etc.) be recognized within the field of Creative Arts Therapy. This also led to developing guidelines and credentials for professionals in the field that are now used in the expressive field around the world.

The Registered Expressive Arts Therapist (REAT) credential is designed for those who use intermodal expressive arts in therapy, social work, and counseling. The Registered Expressive Arts Consultant Educator (REACE) credential is designed for those who are trained in and use intermodal expressive arts in coaching, cultural change, education, healthcare, hospice, organizational development, peace building, social transformation or spiritual development.

The International Expressive Arts Therapists Association (IEATA) established professional guidelines and a rigorous review and registration process. For example, there are supervision hours required for the registered expressive arts therapist (REAT); however, supervision hours are not required for the registered expressive arts consultant/educator (REACE). IEATA has discussed the limitations of having *therapist* in the title of the professional organization. When IEATA was formed in 1994, individual and group therapy were the primary applications of expressive arts. Currently expressive arts therapy is being used across many populations, organizations, and for social transformation and hence, the designation for the Registered Expressive Arts Consultant/Educator (REACE) was devised.

The International Expressive Arts Therapy Association established ethical guidelines that are available at www.ieata.org. Ethical guidelines cover informed consent, qualified competence, moral and legal standard, research, public statement, confidentiality, welfare of the client, collegial relationships, special considerations for expressive arts work, and non-ordinary states of consciousness. All Registered Expressive Arts Consultants Educators (REACE) and Registered Expressive Arts Therapists (REAT) agree to abide by the highest standards of professional practice and to adopt values and goals that support and advance the expressive arts community.

Future of the Expressive Arts Field

There are opportunities and uncertainties in the field of expressive arts, as there are in every field. For example, is there a primary expressive arts discipline that can be taught and mastered in integrative expressive arts? How can an expressive arts practitioner develop competence in such a diverse field? Even though a practitioner may specialize in one art form such as music, movement, writing, or visual arts, he or she cannot have expertise in all of the arts.

Should expressive arts practitioners use the existing theoretical foundations in the fields of psychology and creativity, or establish a distinct field? Who determines requirements for credentials in the field? As the field of expressive arts becomes more well-known, numerous certificate programs emerged around the world with a wide variety of philosophies, educational processes, and costs. Some expressive arts programs are accredited through a host university and students receive graduate credits and degrees. Other programs are not accredited, and the student pays tuition without knowing if the certificate that is awarded will be viewed as

a genuine credential. Funding challenges may exist for the students, educational institutions, and the organizations who want to incorporate expressive arts into their programs.

As the field continues to evolve it is important to stay grounded in the history of using intermodal creative processes to foster healing, personal growth and social change. With tested applications in counseling, coaching, consulting, education, psychotherapy, and social change expressive arts has a promising future. Engagement in expressive arts can awaken our innate creativity and activate our imagination and intuition, leading to the development of our higher human potential.

The Importance of Failure

Although creativity is often thought of as a good thing, and failure as a bad thing, in reality, they are interlinked. Failure cannot be avoided when being creative and can in fact be a positive force in driving human creative endeavor. The world's most successful and creative people have failed while on their journey, and often done so spectacularly and painfully. This chapter therefore examines the place of failure in creativity.

Failure in a creative endeavor can be encountered at many points in the process. Such failure is often linked to differences between the creator's perception of the work and the perception of others. The environment also has a place in failure and creativity. The creative industries are used in this entry as a significant example, but it is also noted that creativity and its role in innovation is important to a wide range of organizations. In particular, the difficulties of supporting failure without damaging reputation are exposed. On the basis that not everyone (or every organization) will respond to failure equally, the entry looks at the characteristics which suggest a more effective response. These include individual traits, behaviors and attributes ranging from knowledge to resilience. It is also the case that the environment plays a significant part in enabling a creative response to failure and so the entry finally examines how creative response can be fostered by organizations and networks.

The Meaning of Failure in Creativity

Before examining the relationship between failure and creativity, a definition of failure must be reached. Most people would be familiar with the example of a feature film (which involves significant creativity) being termed a "flop" if it failed to achieve box office success. However, the reasons for such a commercial failure (though difficult to highlight exactly) could be attributable to issues at various points in the process ranging from a poor script near the start, through to misguided directing while filming or ineffective marketing post-release. Incidences of failure and the opportunity to respond creatively are therefore more widespread than initially thought.

To illustrate this point further, the practice of sculpture (which most people would consider to be highly creative) can be used. If a sculptor accidentally broke-off the head of a sculpture, this could be considered a failure in applying appropriate techniques. However, if the same sculptor completed the work without such a mishap, but then failed to sell it, it could still be considered to be a failure. These failures occur at very different points in the process, but they both present the opportunity and need to respond creatively - the only other alternative is to give up. The point at which failure occurs in the process, and the nature of that failure means that the response is likely to be varied, hence the need for greater insight into failure and creativity.

Failure is usually defined in three ways - a lack of success, the neglect of some action expected (for example, when something was not completed on time), or something ceasing to work (such as a computer malfunctioning or a business collapsing). Failure and how it fits into creativity can be considered in relation to these three definitions.

First, to consider the "lack of success" definition, the example of the production of a "creative" artifact such as a painting or a piece of music can be used. Here, if the ultimate result were to be badly received critically or commercially, it would be seen to have failed. Crucially though, the creator may have considered it a huge success up until that point - the failure may therefore come as a surprise

and initially, it may seem that their labor has been in vain. If he or she is still committed and have the resources (time, ideas etc.) however, the creator can respond creatively to find another way forward. In doing so, the hope is that their effort so far is not completely wasted and that the likelihood of success will be greater.

To illustrate the second definition, the same creative practitioner may fail to deliver the required artifact to their client or audience when it is expected. This could be due to any number of problems in the production process. Importantly though, the creative practitioner would know that they were going to fail – it would be no great shock. Indeed, their conscious or unconscious actions during the production process may have contributed to the failure. They may argue that events have taken the better of them or some unforeseen problem occurred, but again, their inability to respond constructively would have played a part in the failure.

Taking the last definition, the creative practitioner may experience the failure of a crucial piece of equipment while making the artifact, or the business that has commissioned the work may go bankrupt partway through the process. Although this type of failure (of an inanimate object or organization) seems out of their control, there are still options to respond creatively to take the work forward. Examples could include adapting to using a different piece of equipment to that which has failed, or changing the work sufficiently so that it can be sold to a different organization.

Time, context, and the perception of creative work also have a significant bearing upon creativity. In terms of time, many services or products which have been realized using a creative process begin to fail as society and technology moves forward in new directions. An obvious example would be in the creative practice of car design – an older design considered good in its day may now fail to adhere to safety or emissions standards, or fail to sell because of better competition. In this particular field of practice then, the car designer needs to respond creatively to the failure of previous generations to develop a product which is future-proof. Otherwise, any new design is also likely to fail in some way. Context and perception are also a crucial part of the picture. For example, a creative product may sell well in one part of the world but for cultural or economic reasons, be a commercial failure in another. Such complexities can make responding to failure (or the potential of failure) with creativity somewhat challenging.

While the focus of this chapter is on failure, it is useful to place this in the context of a definition of creativity. Over the years, many authors have sought to define creativity, including [Runco and Jaegar \(2012\)](#), [Csikszentmihalyi \(1997\)](#), [Robinson \(2009\)](#), and [Robinson and Aronica \(2009\)](#). While the audience for such authors' work is slightly different, they agree that the common definition of a creative idea is one which is new and has some usefulness. So while the obvious focus of creativity is often on artistic or cultural pursuits such as music or painting, this need not necessarily be the case. In fact, the "new" and "useful" ideas which creativity generates can be valuable in many spheres including some which many people would not immediately think of as "creative". Whatever the field however, the crucial question is how a person or organization deals with the inevitable failure as part of their aim to generate ideas which are "new" and "useful".

Environment and Its Role in Failure

The definitions of failure have shown that although failure can take place through the actions (or non-actions of the individual), the external environment also plays a significant role. Therefore, although many people, irrespective of the type of work they do have some chance to be creative, the creative industries will be used here as they provide the most striking illustration of the role played by the environment.

In the creative industries, work is constantly appraised, shaped, and consumed through the function of gatekeepers or what authors such as [Bourdieu \(1984\)](#) term as "cultural intermediaries". Though not producers of creative work themselves, cultural intermediaries bridge the gap between creators and consumers and therefore decide what will be successful and what will fail. While there are differences between the various parts of the creative industries, some common practices exist. For example, an author will need to have their book commissioned by an editor, and a musician seeking a recording contract will need to be contracted by an Artist and Repertoire (A&R) Director. These cultural intermediaries do not commission work "cold" however. Instead, the creative practitioner will bring a creative artifact (for example, a book manuscript or music recording) to them for the purposes of securing a legal and commercial agreement. Up until this point though, they may well have been working creatively in isolation.

A number of factors therefore contribute to the potential for failure in this scenario. First, now there is often a significant "gap" between when a creator undertakes their work, and when it is consumed and this can give rise to a potential disconnect. Taking musical performance as an example, prior to the invention of sound recording, a musician's only outlet would be performing to an audience, from which the response would be immediate and palpable. Capturing a musical performance on record changes this dynamic, as the musician has no audience reaction upon which to build their creativity. Instead, they rely on the cultural intermediary to "reflect" and communicate to them what they think will be creatively or commercially successful. The same situation exists in acting when comparing a theater performance with acting in a film. In these examples, there is more vagueness as to what is viewed as "creative" and this increases the likelihood of failure. Secondly, the creative industries have a poor record on being able to forecast what will be successful and what will fail commercially. Taking the example of the music industry, a very high percentage of recordings produced make a loss, and it is the small percentage of successful ones which are essential to subsidize the failures. It is therefore an industry which demonstrates a poor ability to forecast what will be successful, the result of which is that commercial failure is common. The same can be said for many other example sectors such as film and television production, book publishing, art or theater. A final factor is that the creative industries are very attractive to potential workers who gain high

levels of personal fulfillment due to the nature of the work. The greater the number of potential workers seeking financial support or rewards for their work, the greater is the likelihood of failure for anyone seeking to start or sustain a professional living in a particular sector of the creative industries.

When focusing on the “where” of creativity, the work which Csikszentmihalyi (1988) published on the systems level of creativity is particularly significant. Csikszentmihalyi outlined how creativity sits at the interface between the individual, and what he calls the field and the domain. The field is made up of a specific community of practice (including its gatekeepers) and the domain is where the knowledge and culture exists. The manner in which these elements relate to each other is summed up:

For creativity to occur, a set of rules and practices must be transmitted from the Domain to the Individual. The Individual must then produce a novel variation in the content of the Domain. The variation then must be selected by the Field for inclusion in the Domain

Csikszentmihalyi (1999): 315.

Failure to be admitted into the domain by the gatekeepers therefore means going back to the drawing board and coming up with another creative approach, idea or solution. To do this, the creative practitioner may need to draw upon the domain for the required knowledge that will then feed into the solution – it may therefore be the case that they need to acquire greater knowledge of the domain. The important aspect to note however, is the influence of the domain on the work produced, and the influence which the field (in the form of gatekeepers) has on whether work is successful or not – this is termed as “situated creativity”. Csikszentmihalyi is not alone however, and other authors have also noted the manner in which creativity needs to find support and influence. Two notable examples of this are Sawyer (2006) and Sternberg (2006). Contrary to what most people immediately think, both of these authors point out that getting ideas to be accepted is often more difficult than coming up with ideas to start with. This is also why Simonton (1995) added persuasion to the existing four P’s of creativity.

Many people have the potential to be creative in their work and everyday lives, and so it is important not to just focus on the creative industries. Creativity is also of value to the wider business world and is the process through which the novel ideas which form the basis of innovation are made possible. This often takes place where individuals rather than working in isolation, collaborate to come up with “new” and “useful” ideas. This tends to bring even more complexity to the situation and indeed, opportunities to fail in many ways (sometimes centered on the individual, other times on the organization). This concept of group creativity and how the environment is key is examined in detail by Paulus and Nijstand (2003). Here, in the first part of the book they focus on how group creativity takes place and how it can be inhibited or supported in any number of ways. The second part deals with issues associated with the environment and context, in overall acknowledgment that group creativity cannot be adequately understood without due consideration of where it all takes place. Creativity is also linked to innovation and entrepreneurship. However, unlike the creative industries where “critical” acclaim for creativity can be seen as valuable, in the wider business world, creative ideas need to have a more straightforward grounding in utility, and contribute to the “bottom line”. In order to have this type of functional utility, creative ideas need to provide an appropriate response to some sort of problem or gap in the production, marketing or logistical processes of an organization. As noted earlier, in meeting such a need, the creative response can be to a failure resulting from decisions made in the past. However, the means to achieve it lie in the organization as a whole (rather than just the individuals in it) being creative. It therefore involves organizational rather than individual creativity whereby a complex social system and organizational structure comes into play.

Although failure is an inevitable part of creativity, unsurprisingly, organizations (just like individuals) prefer success to failure. In fact, companies and organizations do much to foster an image of success – from the high consumer rating of products and services through to how the business is run. For companies quoted on the stock exchange in particular, a public perception of failure can have a massive negative effect on share price, the ability to borrow money or even the potential to attract new employees. This could lead to the situation where employees and managers ignore or avoid failure for fear of attention from the organizational leadership or the external world. This is a mistake however, because as authors such as Sitkin (1996) noted, failure plays an essential place in an organization because it creates recognition for risk as well as a motivation to change (most likely involving creativity). Sitkin also noted that organizations need to be aware that not all failures are equal and so should therefore take steps to actively “manage” failure. The most effective outcomes occur from failures which have the following five characteristics: (1) They result from thoughtfully planned actions that (2) have uncertain outcomes, (3) are modest in scale, (4) are executed and responded to with alacrity (eagerness), and (5) take place in domains that are familiar enough to permit effective learning.

Responding to Failure With Creativity

Individual Response

In recent years, failure as a route to success has gained attention in the academic literature as well as in more “mainstream” publications that aim to encourage their readers not to fear failure. For example, Matson (1991, 1992) has written extensively about Intelligent Fast Failure and how taking such an approach can enhance innovation and creativity in a variety of organizational environments including schools, Universities and workplaces. In essence, Intelligent Fast Failure is a process of trial and error taken until a satisfactory solution is found. An example of a publication with a broader target is that of Harford’s (2011) book, *Adapt: Why*

success always starts with failure. Harford argued that the sheer bureaucracy of the modern world bogs down and slows up innovation, while bad practice and poor decisions are allowed to flourish in dysfunctional markets. The argument is that if things were allowed to fail, and people admitted their mistakes, the result would be better practice and more innovation. What these authors highlighted in their different ways however is that failure needs to be accepted as inevitable (and even attractive), in order for creative solutions and ideas to be produced.

Examples of people who have responded to failure effectively range from those of history through to the present day. For example, Edison, the inventor of the light bulb produced 10,000 prototypes before the one that worked was discovered. He noted "I have not failed. I've just found 10,000 ways that won't work. I am not discouraged because every wrong attempt discarded is another step forward." Similarly, Henry Ford said, "Failure is only the opportunity to begin again more intelligently." In more recent times, James Dyson, one of the world's leading designers and industrialists produced 5127 prototypes of his first vacuum cleaner before arriving at the effective solution. From the world of popular music, Nile Rogers has stated that "the way I cope with failure is to make another hit". While these people obviously demonstrate the ability to just keep going despite the setbacks, there is likely to be more to their approach than that. They are responding to each failure with creativity where many others would just give up. This gives rise to the question as to why some people and organizations creativity turn failure into success, and why others are less able to.

Dealing with failure and still being creative is far from easy, so the question firstly arises as to what type of person is most likely to be able to do this. According to [Amabile \(1989\)](#), and [Furnham and Bachtar \(2008\)](#), the traits associated with creativity are divergent thinking, openness and preference for challenge. These traits apply directly to how someone deals with failure. For example, divergent thinking involves formulating as many solutions as possible rather than following a convergent thinking approach which would tend to involve working through incremental, logical and clear steps. Engaging in divergent thinking means an individual is not bound by approaches which they or others have taken before (successful or otherwise), and instead, thinking of novel new ways of doing things. When experiencing failure, taking the same approach will simply result in further failure so the greater and more varied the number of options, the better. To do this, the individual must draw upon their own experience and knowledge and so the greater this is, the more likely it is that a solution will be found. In addition, a greater level of knowledge and experience will also provide confidence in going forward.

The person experiencing failure can also look to other fields for ideas or inspiration, and it is here that the concept of openness arises. Having openness means that they will be able to synthesize approaches from different fields and apply them to the problem in hand. This demands critical thinking skills not only to take in the information and process it, but also to apply it in a flexible way. Last, and perhaps most crucial to dealing with failure is the preference for challenge trait. By definition, a challenge is something which must be overcome with thought, ingenuity and effort. A given challenge could involve overcoming the failure of others or the non-functioning of existing systems. Not being able to overcome the challenge could also end in failure and so, a preference for challenge is intertwined with being able to engage with failure or the potential of failure. Certainly, the type of person who falls at the first hurdle and avoids challenges is less likely to be creative. This is because they are unable to draw upon their own expertise to deal with failure, and not open to looking for ideas and inspiration elsewhere in solving the challenge.

[Sternberg \(1985, 2006\)](#) noted that creativity depends upon six distinct but interrelated resources: intellectual skills, knowledge, thinking style, personality, motivation and environment. Intellectual skills and knowledge can be thought of as the "mental" resources, which can be used to find creative new ideas and solutions. In dealing with failure as part of a creative process then, the greater the intellectual skills and knowledge the person has, the more likely they are to be able to move forward creatively. These internal resources which are drawn upon can be developed deliberately through personal improvement and learning such that the level of expertise is fit for the challenge. However, the more experience (including that of failure) a person has, somewhat ironically, the more they can develop their expertise. Taking the example of an inventor who constantly fails to get each prototype to work but carries on to the next one, with each failure, it is not only the prototype which gets better, but also, the inventor's capability to a point where they become more expert than anyone else in the field.

Sternberg's concept of thinking style resonates with how divergent thinking supports creativity. The manner in which someone's thinking style can help or hinder their approach to failure in the creative process is therefore pivotal. At one extreme, a divergent thinking style is flexible and is based on a heuristic approach to the problem. This type of thinking style which looks for innovative ways to solve problems is more likely to be creative and solve problems. At the opposite extreme, a type of thinking style which is rigid, narrow, and fixed upon prior approaches is unlikely to find creative ways to solve problems and is more likely to fail.

Personality, motivation and environment are also important elements. Personality characteristics pertinent to dealing with failure include resilience and confidence that creativity can be used to find new solutions. The quotations from inventors and industrialists show their unwillingness to allow failure to stop them. However, because of their intellectual skills and knowledge, such people possess the necessary confidence in their own ability to solve problems and move forward. This may be because they have found their way through problems in the past, and although they do not presently have a solution, are confident that they will come up with one. Additionally, the further through the process of developing a product, idea or service they are, the more expert they have become and this can also be a source of motivation as they near the end with increased confidence.

While motivation to be creative is important, the concept of resilience goes beyond this as a predisposition for dealing with failure. Resilience is the manner in which an individual (or an organization) "bounces back" from a setback, problem or barrier. Creative practitioners can experience frequent and significant setbacks, and similarly, those who seek to be creative within an organization may find their ideas are rejected or not valued. Even the most creative or talented person may give up at some point depending upon how resilient they are.

Interestingly, the value in creativity in developing resilience has gained attention by researchers in the field, including Metzyl and Morell (2008). Here, the pursuit of creativity is explored as a way to deal with trauma or setback by providing a way or release, escape or distraction. It is suggested that creativity can be used to not only solve problems, but also, that deep down, engaging with creativity can be a way of processing rejection, failure or even traumatic life events. This does however depend upon the focus of the creativity. If the creativity is related to solving a problem or dealing with a failure, then it could be considered to be moving forward and finding a solution. However, if creativity is merely an “escape” from a failure or problem, then the problem will remain unsolved. As Metzyl and Morell noted, this may help the person engaged in creativity personally, though this may not be related to a work challenge. Taking the example of the creative industries, the result of this may be that the domain rejects the work while in the wider business world, the creative results may not find support, as they do not contribute to the bottom line.

Environmental Support for Responding to Failure Creatively

As this entry has outlined, creativity does not really take place in isolation as the environment has a crucial role. It follows therefore that the environment has a crucial role with respect to failure. For the individual “creative”, failure is often decided upon by the complex systems of cultural intermediaries and shifting markets. For someone employed within an organization, it is the organization’s structures, processes and culture which have the potential to accept failure as part of the process and support creativity.

For the individual creative practitioner such as a musician or artist, considerable problems can occur due to working in isolation and this often contributes to the likelihood of failure. Many people are familiar with artists such as Van Gogh who were not particularly successful during their lifetime, and yet kept going, only to receive critical acclaim after their death. Alongside obvious talents, examples such as these demonstrate resilience and commitment to their work, and the ability to not be discouraged by failure. The individual creative practitioner actually has considerable potential to “shut-out” the world and can get to the end of the process of producing a creative artifact without much interaction. This does however, increase the likelihood of failure and by doing so, the creative response is more of an ignoring of, rather than constructive response to failure.

Instead, a creative response to failure has to take account of the fact that today, the production of creative goods takes place within the creative industries with its complex system that serves to define what will be successful and what will fail. The creative practitioner may get little in terms of prompts, information or support to mitigate against, and respond to, failure. However, at some point, the system will present them with failure to which they must respond, drawing upon their own resilience and capability. While failure could be of their own doing, the role of the domain in deciding what will be admitted and therefore successful is crucial. It follows therefore that an understanding and appreciation of the domain is vital. The domain can be difficult to understand or infiltrate though, so the creative practitioner needs to find ways of mitigating against, and of working with, failure. One of the ways of doing this is by being a part of networks or guilds made up of their peers. Such “organizations”, however informal, can support the creative practitioner by being a source of knowledge, information and prompt as to how to go about their work. Rather than working in isolation then, the work can be better aligned to what the domain will find acceptable for admission. For creativity, the environment is also a source of ideas, inspiration and solutions to problems, and such creative networks or guilds can provide this. Mitigating against the risk of failure through isolation is particularly important today where more creative workers utilize new technology to work remotely. This is because the problem of working remotely using new technology is actually twofold – firstly, likelihood of failure is increased due to the isolation and secondly, engaging in creativity can be more difficult because of the lack of social interaction in which creativity best takes place.

As was noted earlier, many people (other than creative practitioners) have the opportunity to be creative in their work, and organizations need to value creativity for its role in innovation. As failure plays a part in this, organizations need to accept its inevitability on the precept that it will ultimately lead to innovation. In a practical sense, this can mean allowing time for employees to think, providing support with resources, communicating encouragement and allowing freedom from criticism of failure. This will not just allow individuals to generate creative ideas, but also enable relationships and collaborations to do the same. Clearly, this situation is complex because an individual is unlikely to want to be seen to fail in front of those with whom they are unfamiliar. Failure may also be seen badly in the eyes of those higher up in the organization. For these reasons, there is considerable danger in employees coalescing around innovations with a lower risk factor rather than those they know to be riskier. At the other extreme, employees who are highly creative may involve themselves in risky projects for their own personal satisfaction whereas ultimately, these bring little economic or logistical benefits to the organization. Again, unfocussed creativity may fail in its contribution to the organization because it is not a direct response to a problem or gap in the production, marketing or logistical processes of the organization.

It follows that the culture of the organization has considerable influence on how failure is tolerated and therefore how much creativity flows from it. Organizations which are rigid may well not be interested in creativity and may also not tolerate failure. The organizational structure, lack of feedback or guidance, lack of budget, lack of recognition, and amount of red tape or bureaucracy can be behind such a situation. Such organizations may therefore foster behavior which inhibits creativity with people who are not keen to be inquisitive or question assumptions and instead, exhibit a tendency to conform. It does also, of course depend upon industry sector and how far through any given process creativity and failure occurs. For example, many software companies are known for releasing new versions of their software which are not fully developed. Instead, they rely on new users to find bugs that they then go back and fix. Here, the creativity of the programmers responds to the failure discovered by users. In many cases, new features not thought of by the programmers themselves can be later included. By way of comparison however, the Pharmaceutical industry would take a different view (as do the regulators governing their work) and only sell products that they believe to be relatively risk free as the ramifications could include a degradation of health or even death in their users.

Some factors under the control of the organization can interestingly foster or inhibit creativity. For example, a lack of resources could work either way. While creativity generally needs resources (whether in terms of time or tangible support mechanisms), authors such as Runco (2004) have noted that a lack of resources can force creativity to take place. It is a similar situation with competition. Generally, competition stimulates creativity. However, if intense competition in the marketplace makes new ideas, products or services obsolete before they make back their investment, the creativity to produce such things could be discouraged. Here, fear of failure actually inhibits creativity, at least in the short term.

The concept of resilience and how it relates to failure also applies in an organizational context. Here, it reflects the organization's ability to absorb and respond actively in order to make the most of unexpected and disruptive events which could threaten its survival into the future. The rapid change in technology and global disruption means that organizations face more turbulence than ever, and many scholars noted that creativity is essential in responding successfully to such turbulence. Richtnér and Löfsten (2014) examined this concept in depth, specifically how a capacity for resilience influences creativity. Based on their findings with a breadth of organizations, they noted that in order to be resilient and for creativity to be fostered, organizations need to address two aspects. Firstly, adequate skills are needed, knowledge must be present and (as cognitive resources) these must be developed over time. This enables the right person or resource to be matched to the problem in hand. Secondly, trust, respect and collegiality (as emotional resources) must be present. The authors acknowledge however, that it is much easier for an organization to develop structural resources than the "softer" aspects such as trust and collegiality. Overall however, the conclusion is that organizational resilience is found to be positively related to organizational creativity.

Glossary

Authoritative parenting A style of parenting characterized by high expectations and rules as well as freedom and flexibility. Dialogues about the rules and boundaries are also encouraged.

Child-centered families Families who spend a vast amount of time, energy, and resources on developing their children's interests and enriching their experiences. Some parents want to insure that the children they perceive as gifted receive early instruction in their domain of giftedness.

Complex families Families characterized by a balance between integration (i.e., seeking support and warmth) and differentiation (i.e., seeking independence as well as developing one's own identity and interests).

Eminent creativity Characterized by such originality and novelty that it is recognized by a certain field as being culturally significant, and being remembered for altering a domain.

Enriched environment Home environments characterized by books and multitudes of other intellectually stimulating resources. Parents typically read to their children early on, hold serious discussions with them, and take them to interesting places such as museums, zoos, and theaters.

Everyday creativity Characterized by originality and uniqueness as well as meaningfulness and usefulness in day-to-day life. It might not revolutionize a field, but it makes a difference in the creative person's life.

Resilience The ability to function competently in a stressful situation that threatens development and adaptation. It has also been defined as the ability to recover from trauma.

Introduction

Families are lambasted or exalted in numerous works of arts including plays, novels, songs, and operas. They are depicted mercilessly or indulgently in paintings. Playwrights, novelists, songwriters, composers, and painters hold particular views of families that may or may not be reflected in their work. Certainly, their families shaped their creative evolution. For example, Mozart's father resolutely turned away from his own (admittedly flailing) career and devoted himself almost exclusively to his son once he recognized the boy's talent. Similarly, Picasso's father allegedly pledged to stop painting once he realized that the 13-year-old boy was better than him. He then dedicated much time and energy to his son's artistic education. Freud's mother adored her son and the family life was strictly structured around his early work habits.

Whether these eminent creators would have become equivalently eminent had their family circumstances been different is as intriguing as it is unanswerable. However, the influence of the family on the lifelong development of creative talent does not show just uniformly pleasant childhoods. In part for this reason families have received much theoretical and empirical attention.

[☆] *Change History:* August 2019. Mark Runco updated the text throughout.

This article is an update of A. Kohanyi, Families and Creativity, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 503–508.

That is the focus on this entry. It reviews family characteristics and the role of stress in the early lives of creators. It also examines the set of responses that creative children develop as a reaction to stress and how this very set of responses shapes creative development. This entry ends by presenting a framework that ties together the overarching themes reflected on in this article. Even though it is generally accepted that creativity requires the input of both nature and nurture, the hereditary aspects of creativity are outside the scope of this entry (see Piffer and Hur, 2014).

Parenting Style

Parents who are warm, involved, caring, and yet willing to give their children the freedom to explore at their own pace are more likely to have creative and imaginative children. Parents of creative children who scored high on creativity tests and were labeled as creative by their teachers seem to be less overprotective and more tolerant of the hostile feelings their children may direct toward them compared with parents of other students. Naturally, many children labeled as creative do not necessarily become eminent creators. Parents of creative children are, in general, well educated, successful in their careers, and self-confident. Moreover, parents of creative achievers tend to be relatively egalitarian, and creative young people themselves are less concerned about following rigid sex roles. Thus, they also seem comfortable considering activities and fields that are not typically associated with their gender. Empirical work by David Harrington supported this idea with correlations between family life, creative talent, and psychological androgeny (a balance of masculine and feminine traits).

Families favoring independence are likely to have creative children. Indeed, highly original children are encouraged to be independent from their earliest age (Albert & Runco 1989). Parents who value independence are also usually receptive to unconventional thinking and to particularly imaginary play, such as involvement with imaginary companions and imaginary worlds. This form of play is associated with various forms of creativity in adulthood. Thus, it seems that the child rearing style of creative achievers' parents tends to be less conventional, and more flexible, which promotes originality, and freedom of expression. Although they might appear lax, rules and expectations are firmly in place as well within these families. This style of parenting is sometimes referred to as authoritative, and is characterized by the presence of both boundaries and flexibility. Boundaries give children a sense of security, while flexibility offers children the freedom to discover, explore, and play, all of which have been associated with problem solving. The Authoritarian style of parenting is somewhere between authoritative (where parents make all decisions) and laissez faire styles (where parents are largely uninvolved).

In sum, parents of creative children have a particular approach to parenting. Likewise, they have a specific approach that is conducive to the development of creative potential, as evident in their interactions with their children, their home environments, and the experiences they choose for their children.

Family Background

Creative individuals tend to have encouraging parents who were likely to be financially and culturally privileged. Finances, and more generally, socioeconomic status (SES), is relevant to creative development because it influences the material resources available to the child, as well as whom the child is exposed to, how much travel he/she engages in, and which institutions the child visits (Dai et al., 2012). There is a discussion in the literature that is consistent with the idea that "necessity is the mother of invention," the implication being that a lack of resources may sometimes stimulate creative thinking. But data are more aligned with the first view, where resources are readily available.

Notably, SES is related to education. Parents' level of education impacts what is discussed at home and how. It also carries the message that education is highly valued in the family. Another aspect of SES is economical. Families with significant resources may be less concerned about gearing their children toward high salary careers and are willing and able to support nontypical interests. SES may have an effect on richness of experience, which has been related to divergent and flexible thinking.

Creative achievers generally come from enriched, child-centered environments. Parents support and encourage children and are dedicated to the development of their child's creative talent. The climate at home is very stimulating, with books and a multitude of other resources readily available. Parents make a conscious effort to regularly expose their children to various venues illustrating the richness and diversity of the life of the mind. Parents take their children to zoos, theaters, concerts, museums, and libraries. Creative achievers' parents respect learning and the pursuit of intellectual and artistic interests. They tend to be creative themselves in addition to broadly curious. These parents often love challenging debates, and are typically busy in cognitively demanding activities. They engage their children in serious discussions about complex matters. Parents also regularly read to their children from their earliest childhood. These parents respect their children's opinions and consider what the children say and do as important. Hence, they regularly collect their children's work and highly value it. They also encourage their children to be independent, and foster model values such as discipline and hard work.

Thus, through interesting books, enriching experiences, and stimulating conversations, creative children develop a certain understanding about the world that lays the foundations for the acquisition of further knowledge. A wealth of knowledge is indeed considered a prerequisite for many creative endeavors. Moreover, a child centered environment builds the child's self-confidence and makes him or her feel valued and loved. Harrington's research, mentioned briefly above, also found an association between a home life with *unconditional positive regard* and the development of creativity. However, a child centered environment does not

preclude that tensions exist between parent and child, or that the child's life might be stressful because of other types of adversity of various degrees of seriousness. One type of stress is the presence of siblings.

Birth Order

In some families, particular children are clearly favored over others. This can lead the less cherished offspring to express their frustration creatively. Their creative efforts may attract attention and allow these creative children to distinguishing themselves from their siblings. Indeed, birth order plays an important role in determining family expectations and resource allocations. Robert Albert described birth order, as well as family or sibsize, as family structural variables. He contrasted these with process variables including things like parenting style or discipline style. Birth order has received more attention than any other variable. It can also establish which child will occupy which niche within the family, including who will be deemed the 'creative one.'

There is a lack of consensus within the literature with regards to creativity and birth order. First born appear to be more creative based on some studies whereas others claim that it is later born who hold this merit. Another position is held by scholars who suggest that family size, age differences, and sex differences are the mediating factors in the birth order-creativity equation (Bender et al., 2013). Frank Sulloway, in *Born to Rebel*, argued that birth order affects the various stratagems that siblings concoct in order to win parental approval. Indeed, the overrepresentation of first born among creative achievers could be attributed to their special status within the family. As first and only children, they received all the attention from their parents and enjoyed all resources available. They are thus motivated to hold on to this privileged position when siblings arrive. They do so by identifying with parental authority and accepting the power structure within the family. They often act as surrogate teachers to younger sibling(s) to further please their parents, which gives them experience with responsibility and maturity. First born typically demonstrate early focus, and are more academically and achievement oriented than later born.

The exceptionally high number of last born among eminent creators might be due to birth order as well. As the youngest in the family, the last born also received notable parental attention, perhaps because he or she is the last child the parents will ever have. Last born, precisely because they are later born and never received undivided attention from parents, tend to be indifferent to power and to question and challenge the *status quo*. Middle- and last-born children tend to be more rebellious than first born, who have clear conventional and conforming tendencies. Indeed, last- and middle-born must carve a distinctive place for themselves within the family sphere, and must experiment to discover their niche. Hence, they adopt a personality style and field of study that are distinct from that of both first born and parents. Sulloway demonstrated how often middle born children have led rebellions and attributes this to their experience at intentionally going in a direction that is different from others. Given that first born children tend toward the conventional direction, that leaves the unconventional niche for middle-born children, and this often supports rebellion and creativity.

Later born are thus much more likely than first born to accept and embrace new and revolutionary ideas (i.e., Darwin's theory of evolution). Whereas first born do not support radical revolution, later born do not back conservative ones. Likewise, first born demonstrate their creative brilliance within a field's accepted paradigm, while later born exhibit their creative virtuosity outside the *status quo*. First and last born also differ in the expression of their creativity through the two dimensions of openness to experience. Indeed, Sulloway proposed that birth order relates closely to this personality trait so that first born use the intellectual dimension of openness to experience (i.e., perceptiveness, curiosity, and culture) and later born the nonconformist dimension (i.e., risk taking, unconventionality, originality, and independence).

There are also domain differences: first born are disproportionately represented among eminent scientists, and tend to excel in the physical sciences, possibly because problems are well defined within this field. Numerous eminent scientists are last born as well, although less so than first born. Last born are more altruistic than first born, and thus likely to excel in domains that are socially oriented. They often prefer the biological and social sciences, where problem finding plays an essential role. In addition, last born tend to work simultaneously on multiple projects that often cross boundaries. When they win the Nobel Prize, it is in domains such as peace and literature, whereas first born tend to be honored for their contributions to the sciences.

Birth order therefore seems to influence the personality of siblings because it shapes the approach they select to win parental favor. Thus, for Sulloway, birth order ultimately contributes to the ways first and last born reach creative eminence. Creative children may also face much more taxing situations than competition with siblings. (See Birth Order).

Stress, Trauma, and Adversity

Creative and academic achievers (meaning, children who do well at school) present very different family profiles. The latter's families tend to be more stable, child centered, and favoring a conventional style of parenting. The former tend to come from troubled family backgrounds, where the relationship between family members is tense, the parenting style unconventional, and the likelihood of parental dysfunction high.

Indeed, studies on the childhoods of eminent individuals based on material culled from biographies and autobiographies reveal adverse family environments. Victor Goertzel and Mildred Goertzel examined the home environments of 400 eminent individuals, and then 317 additional ones. Forty-four percent of the entire sample of 317 eminent people experienced a stressful childhood, including a majority of the actors, novelists, composers, musicians, explorers, athletes, philosophers, and psychologists. For

example, as children they were raised by single parents, moved frequently, witnessed parental alcoholism, fights between their parents, and other forms of family trauma. They experienced poverty, prejudice, and racism. They were the victims of neglect, abuse, and abandonment. They suffered from the loss of a sibling or of one or both parents, mental illness in one or both parents, and suicide in the family. Only 58 out of the 400 individuals studied by Goertzel and colleague had a normal, loving, and supportive family, which led the authors to conclude that a happy home environment does not predispose one to become creative. Limitations of studies based on biographical and autobiographical material are well documented, and the individuals reviewed by Goertzel et al. were eminent, which does not necessarily imply that they were creative.

However, these studies are not alone in their claim of a relationship between creative individuals and traumatic home environments. For example, Robert Albert found that a higher than average percentage of creative individuals experienced parental loss early in life (30% of eminent people studied suffered the loss of one parent, as compared to 8% in the general population).

Creative children are likely to experience more tribulations than their equally bright but less creative peers. It has even been intimated that a certain tension between parents and children furthers independent thinking, whereas a harmonious relationship tends to promote a more conventional thinking style. Children's response to stress may both be influenced by and play a role in determining the development of their creative potential.

A distressing family environment does not automatically result in creative outputs. Indeed, William Therivel affirmed that different types of childhood afflictions may result in different outcomes. For example, trying relationships with parents, early parental illness, parental absence, or parental loss are tragic and painful for a child. However, these forms of adversity will not lead to feelings of hostility toward parents and other adults. Abuse, on the other hand, will often elicit strong opposition to all forms of authority. Individuals who underwent this type of trauma might be creative in their lifestyle, but will not be engaged in significant creative pursuits.

Children who experience a strained relationship with their parents may try to minimize contact and turn to intellectual and creative activities for solace. They are likely to feel in control within their domain of predilection. This feeling may help partially remedy the lack of control that they experience in their everyday life. They also involve themselves in creative pursuits to fulfill their emotional needs. In addition, being ignored or rejected by parents seems to lead to the development of a unique identity, distinct from those of the parents, which appears to be a critical element of the creative personality.

Furthermore, difficult home environments are likely to interfere with the normal process of socialization. Children sometimes have parents who are unable or unwilling to guide them through social mores, appropriate behavior, and rules. They may also fail to enroll them in traditional schools. These children then acquire limited knowledge of conventions, which Therivel referred to as 'scripts.' They are also prone to reject these scripts, and as a result, become autonomous, divergent, and independent thinkers. Further, absence of parents automatically results in children being unable to create bonds and identify with the absentees. Lacking a role model, these children are likely to have more unconventional and unusual lives. More immediately, a problematic home life leads children to feel different.

Solitude

Many creative achievers and other gifted individuals were often rejected by others as children because they were deemed different. Rejection made them hypersensitive and tense. As a result, and because of their particular home situations, they spent a great deal of time alone as children. Time alone has been deemed critical to the development of the creative individual, and children used the time to read, learn, practice, and acquire new areas of knowledge. In addition, many creative and imaginative children who spend quite a bit of time alone develop a rich fantasy life. A vivid imagination is believed to stimulate the use of imagery and visualization, which can be used later to problem solve. Furthermore, fantasy is an effective strategy to cope with emotional and psychological trauma and pain. Within their imaginary worlds, children are able to rectify the ills of their lives and play out scenarios in which they emerge victorious.

Regardless of the cause of their isolation, creative children come to develop a taste for solitude, and eventually even seek it out. This ability to be alone and enjoy it appears to be an important skill to possess, particularly in adolescence, when the lure of the crowd is particularly powerful. More generally, early adversity is likely to prompt children to develop a repertoire of responses and personality characteristics that are not only conducive to creative achievement but also prepare the individual for the risk taking inherent to the creative professions. Furthermore, these responses acquired in childhood may be very useful when facing the uncertainties, difficulties, and marginality often characteristic of the lives of highly creative people.

Outcomes

Children react in a multitude of ways to situations of dysfunction. As adults, they may try to capture the fear and panic and anxiety of their childhoods in their creative works. For example, early hardship could be a recurring theme in the individual's life, a haunting theme that the individual may revisit and attempt to rework and rewrite in a more satisfactory fashion. In addition, individuals may try to compensate for rejection or abandonment in childhood through a high desire to achieve. Indeed, inborn talent in addition to the motivation to surmount adversity might help account for the development of creative individuals who lack family support.

Further, Howard Gardner posited that creative individuals favor a certain level of anxiety and stress because it was a prevalent emotional state in their childhoods. They seem to crave some discomfort in their lives and feel anxious when tension is absent in the situation or within themselves. They then tend to generate stress in their professional and personal lives by engaging in different kinds of behaviors. However, it seems that there also exist creative individuals who did not develop creatively through tension and trauma, but through more conventional routes.

As discussed previously, creative individuals tend to grow up facing adversity. However, there is a certain level of disagreement regarding the topic. Indeed, there are studies proposing that creative achievers also come from stable, happy, and supportive families. Contrary to Goertzel and colleague's findings, these scholars stated that artists, musicians, scientists, and athletes also grow up in healthy atmospheres. Indeed, they claim that the most creative and productive of achievers come from such encouraging contexts. They also argue that outside the art world, there is little evidence of family malfunction. For example, scientists, inventors, and mathematicians are believed to come from stable families. Inventors in particular seem the less likely to have had stressful childhood homes.

These findings are reflected in Rogers' Theory of Creative Environment, which states that for constructive creativity to develop, the presence of two conditions is required: psychological safety and psychological freedom. Psychological safety is fostered when an individual is regarded by his/her environment as having unconditional worth, when the environment is nonjudgmental, and when the individual feels understood. The former is achieved when the individual is allowed to express him or her self freely. Rogers' theory was later empirically supported. According to this theory, the most central element to the development of creativity is for a child to receive unconditional positive regard from his/her family.

There are researchers who support neither the tense and tough home environment hypothesis nor the nice and loving home environment hypothesis and advance instead that happy families contribute to everyday creativity, where people live productive and helpful lives, whereas a certain amount of stress characterizes the background of eminent creators.

Stress and support are not irreconcilable, and it is possible to conceive of a family filled with stress and tension, and yet, giving the child unconditional positive regard and catering to his/her needs, interests, and achievements.

Reconciliation

Stress alone does not necessarily promote creativity, but stress in addition to support is a more likely formula. For example, Cervantes, Picasso, Freud, Einstein, Goethe, Beethoven, Dickens, and Marx are believed to come from such a background. Moreover, although families of creative individuals tend to be tense and stressful, they may also be structured in a way that buffers stress. For instance, parental neglect may be counterbalanced by attentive siblings, relatives, or friends. A child with an abusive parent may receive attention and love from the other parent. Even in situations of poverty, parents of creative achievers frequently attempt to shelter their children from adversity and emphasize the importance of books and education.

Thus, parents interpret the situations for their children, and these interpretations affect how the child will react to the events. In particular, this parental intervention might trigger a certain level of resilience in the children. Their creative talents and the enriched, child-centered home environment may also contribute to these children's ability to navigate difficult times. Resilience does not mean immunity from stress, but rather the capacity to cope well and be able to function even in the midst of adversity.

Further, resilient children and creative children share many characteristics. Indeed, both are likely to be curious, intelligent, and fast learners. They are able to concentrate and problem solve. Both also seem to have good self-esteem, and be independent. In terms of family background, and again, consistently with creative children's profiles, resilient children are close to their parents. These parents are likely to be authoritative, and are loving, communicative, and supportive. They hold high standards, and supervise their children closely.

It is important to note, however, that most childhoods marked by adversity lead to negative outcomes. For instance, poverty can prevent parents from having enough time for their children, and lack of parental involvement and support have been associated with low self-esteem and behavioral problems. Mihály Csikszentmihályi stated that when one has to fight to guarantee basic survival, there is no time and resources left for anything else. In addition, not all creative achievers are resilient since a higher than average percentage of creative writers and other creators suffer from a mood disorder.

Complex Families

Gary Gute, Deanne Gute, Jeanne Nakamura, and Csikszentmihályi applied a conceptual framework called the Complex Families Framework to the family's contribution to creativity. This is a fitting framework to include here because it pulls together many of the ideas and themes visited in this entry.

According to this framework, complex systems seek to both differentiate and integrate in a continual, organic process. Family members differentiate by pursuing their own goals and developing a distinct identity. They value independence and involve themselves in activities that require increasingly more advanced skills. These activities also provide appropriate levels of difficulty. Differentiation includes parents facilitating the discovery of new interests and challenges for their children. Parents also model perseverance, self-discipline, and hard work. Thus, creative children observe their parents fully immersed in hard intellectual work and witness the satisfaction derived from it.

Family members integrate by pursuing harmony and continuity through emotional support. They also weave cohesive bonds with each other by establishing common values, traditions, and goals (Deng et al., 2016). Thus, integration provides support, security, and a sense of belonging. Integration also involves parents supporting their children's interests and skills, spending time with them, establishing values and rules, and responding to failure intelligently. Another aspect of integration involves the heterogeneous backgrounds, geographical or ethnic origins, ideological positions, or personalities of family members. Indeed, Goertzel, and Goertzel highlighted that first- and second-generation immigrants were well represented among the eminent individuals they studied. Likewise, first- and second-generation immigrants distinguish themselves on creativity tests. These findings are consistent with other empirical results suggesting that bi- and multilingualism, bi- and multiculturalism, as well as immersion in a milieu that tends to question or present alternatives to accepted norms and values stimulates creativity. This diversity within the family allows children to experience varied approaches to the world, as well as varied ways of thinking and doing.

Establishing a good balance between differentiation and integration seems imperative. An over-focus on differentiation would favor the development of eminent (and noncreative) levels of talent. An overemphasis on integration would result in stability and competence but neither in talent nor in creativity. Expectations and boundaries need also to be in place to create a healthy structure.

Conclusions

The contribution of the family to creativity begins early in life and continues as creativity progressively evolves during the lifespan. The family may provide a climate conducive to the child's creative talent development. However, being child-centered does not exclude the presence of stress, and stress might elicit specific kinds of reactions and engender particular personality characteristics that are favorable to creativity but also to the creator's tumultuous lifestyle and career. Although trauma plays an important role in the evolution of creativity, it seems that normal, happy families can fuel creativity as well. It is possible that everyday creativity originates from such a milieu, whereas eminent creativity appears to necessitate some level of tension. It also seems likely that creative achievers come from hectic backgrounds that are also loving and supportive. Parents might filter external stressors and interpret the world for their children, and thus render the stress manageable.

Hence, high levels of creative achievement may rely on the desire to succeed, particular characteristics emerging from childhood trauma, as well as the need to fulfill emotional and psychological needs. It may be that a less dramatic balance of support and stress results in other levels of creativity. Creative achievers who lack family support may have to rely on their inborn talent as well as their motivation to overcome adversity in order to succeed.

Thus, elements conducive to the development of creativity in young people include both challenge and support. Young people are then likely to value and take pleasure in hard work and productivity, enjoy what they do, and thus derive self-esteem and feelings of competence from it. It also seems that one of the central aspects of creative people's lives is complexity. Complex families are able to establish a balance between supporting their children and establishing boundaries and rules; spending time with their children and yet resisting controlling them; having high expectations and yet recognizing that experimentation and failure are normal. It seems that families who find the right balance between integration and differentiation offer an environment that is optimally conducive to the development of lifespan creativity. Thus, the family context of creative children is likely to strongly influence whether the individual ultimately lives up to his/her potential or not.

Introduction

Film has been called the “seventh art,” after painting, sculpture, architecture, music, dance, and poetry. Yet the comparison is somewhat misleading given the great antiquity of the other six forms of artistic creativity. Where the six were already well established by the time of ancient Greeks, film did not emerge until the early 20th century. Even then, film was not immediately recognized as an art form. The medium had originally evolved from the application of photography to the study of motion. Later these “moving pictures” became a form of popular entertainment, a transition perhaps best symbolized by the advent of Nickelodeon theaters.

But, as films became longer and more complex, the medium’s potential for artistic creativity began to become realized at the hands of several classic filmmakers. By the 1920s, certain feature-length narrative films began to be viewed as works of art. By the end of the decade, the Hollywood film industry formed the Academy of Motion Picture Arts and Sciences, which soon began awarding Oscars for major cinematic achievements. Not long after the first film festivals began to appear, starting with Venice in 1938 and the famed Cannes Film Festival launching in 1946. During these years film criticism appeared as an independent branch of journalism, and eventually the form received academic endorsement with the appearance of film studies programs at major universities.

By the latter half of the 20th century there seemed to be no doubt that film could claim its proper place as the seventh art. In the United States, for example, the National Endowment of the Arts created the American Film Institute dedicated to celebrating the art of film. Soon AFI was publishing ranked-order lists of the all-time masterworks in the form. Another development that took place in this period was the materialization of “Auteur theory.” This doctrine began in the mid-1950s with the critics of the French New Wave, and it was further developed by film critics and scholars in the US. The basic idea was that film provides an artistic medium in which filmmakers – most often the directors – should express their personal creative vision. This theory gave the seventh art a more even status with the earlier six. Just as painting has Rembrandt, sculpture Michelangelo, architecture Le Corbusier, music Beethoven, dance Balanchine, and poetry Shakespeare, so does film have such creative geniuses as Pedro Almodóvar, Ingmar Bergman, Luis Buñuel, Sergei Eisenstein, Federico Fellini, Werner Herzog, Alfred Hitchcock, Akira Kurosawa, Spike Lee, Roman Polanski, Jean Renoir, and Yimou Zhang.

Although film is now recognized as a legitimate medium for artistic creativity, it has received much less research attention in comparison to the other arts. It is likely that one reason for this neglect has to do with its recent entry into the list of artistic media. Yet another reason may be no less crucial: Film is inherently a collaborative product. Even the core crew and cast consist of dozen of individual talents who must collaborate in the creation of the final product. As an instance of group creativity, it does not lend itself well to the most common research methods, such as laboratory experiments. Indeed, laboratory investigations of film tend to focus on empirical questions that are only tangentially related to cinematic creativity. For instance, a large number of experiments have been devoted to assessing how music can affect the processing of visual information. Despite the importance of the findings from the perspective of cognitive psychology, the connection with cinematic creativity is more remote. As a case in point, empirical

This article is an update of D.K. Simonton, Film, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 509–515.

research by [Simonton \(2011\)](#) shows that the quality of a film depends very little on the quality of the film score. It is possible that the more the music draws attention to itself the more it detracts from the film's overall impact.

The last point raises a critical question: How does one assess cinematic impact? On what basis can one film be called a masterpiece, another mediocre, and yet another a turkey or bomb? This question can be answered more than one way – a point that must be demonstrated next.

Impact Criteria

Scientists who study cinematic impact have a multitude of choices for the criterion variable. For example, investigators will sometimes use consumer surveys or, more recently, popular assessments posted on the Web (e.g., Internet Movie Database “user ratings”). Nonetheless, the vast majority of investigators tend to use one or more of the following three sets of criteria: critical evaluations, financial performance, and movie awards.

Critical Evaluations

Professional critics provide evaluations of the hundreds of films released each year. These assessments are often expressed in quantitative form, most often stars. Thus, one film might get 5 stars, another 2 ½ stars, and yet another just 1 star. This practice permits the direct comparison of the degree of critical consensus. Research has shown that the agreement is extremely high even if not perfect ([Simonton, 2011](#)). For the most part, the best films tend to receive consistently high marks whereas the worst films earn consistently low marks. As a consequence, composite measures using the ratings from multiple critics will exhibit reliabilities comparable to standard psychometric instruments. In addition, the critical evaluations display considerable stability across time. This stability becomes apparent when the assessments published during the film's theatrical release are compared with the assessments published after the film becomes available for rent or sale in video or DVD format. Despite a temporal separation of two or more years, this “test-retest” reliability also compares favorably with that seen in the best psychometric measures. Composite critic evaluations have another feature: The scores tend to be normally distributed, masterworks and turkeys being much rarer than mediocre films. Finally, because critic evaluations constitute expert judgments, such assessments have strong face validity as well. The composite measures can be considered a version of the consensual assessment technique [see Consensual Assessment].

To be sure, critic evaluations have been disparaged as representing elitist evaluations. Film critics seem to prefer foreign-language, small-budget art-house films over the mainstream Hollywood wide-distribution blockbusters. However, this complaint is not completely justified by the research. Critical evaluations are positively correlated with consumer judgments. The main difference between critics and consumers is the quantity of films watched. Those consumers who are avid moviegoers are more likely to concur with critical opinion. Still, researchers concerned about critical elitism can turn to the next impact criterion instead.

Financial Performance

Although film is recognized as art, it must also be acknowledged that the film industry is big business ([De Vany, 2004](#)). Like any business, the goal is to make a profit, and that end is only achieved if the film attracts large crowds of consumers to the movie theaters. Admittedly, films can also earn money through video/DVD rentals and sales as well as television broadcasts and streaming sites. Yet even these earnings often depend heavily on previous box office success. People are more likely to buy or rent a DVD of a blockbuster than a financial flop. Accordingly, financial performance can be used as an indicator of popular acclaim, as distinguished from critical acclaim.

Financial performance can be assessed a multitude of ways. The most common measure is US domestic box office gross. Less common is world gross earnings, which is not always available. Another alternative is the first weekend gross or the first week gross. Yet it should be noted that all of these figures could be misleading without introducing some adjustment for budget (or production costs). Budget is strongly associated with advertising and promotion expenses, and the latter are highly correlated with box office returns. Profit is what is left over after these costs and expenses are subtracted. Usually a film must gross at least twice its budget to become profitable. Consequently, most films lose money in the theaters. If it were not for the minority of blockbusters that reap huge profits, there would be no film industry, at least not without substantial government subsidies.

Interestingly, although critical evaluations are normally distributed, financial performance has a highly skewed distribution with a long upper tail. So poor are the financial expectations for films at the bottom end of the distribution that a significant percentage of the films made each year go directly into video/DVD or streaming, bypassing the theaters.

Movie Awards

The third way of assessing cinematic impact is to use awards [see Awards]. Various organizations offer numerous nominations and awards each year. Besides honors for best picture, these can include recognition for direction, writing, acting – male/female and lead/supporting – cinematography, art direction, costume design, makeup, score, song, special visual effects, sound effects editing, and sound mixing. Some of these awards are bestowed by professional or guild organizations, such as the Academy of Motion Picture Arts and Sciences or the Screen Actors Guild, whereas others are distributed by critics associations (e.g., the New York

Film Critics Circle). The Hollywood Foreign Press Association, a society of journalists, grants the famed Golden Globes each year. Despite the diversity of award organizations, they tend to display a consensus regarding the recipients. The agreement is almost as strong as that seen for critical acclaim, albeit the consensus is greatest for the most salient honors, such as best picture, direction, and acting. Furthermore, the consensus does not extend to awards earned at film festivals. The latter tend to be more capricious regarding the competition.

One major advantage of movie awards is that they provide a more finely differentiated profile of cinematic impact. Critics assign a single overall rating just as the financial records provide a single figure. Although best picture honors are similarly global, the remaining honors are more specific. However, these more specialized awards cluster into four groups: (a) dramatic (direction, writing, acting, and editing), (b) visual (cinematography, art direction, costume design, and makeup), (c) technical (special visual effects, sound effects editing, and sound mixing), and (d) musical (score and song). Some films might receive the major dramatic awards without receiving recognition in the other clusters. It is significant that the dramatic awards correlate highest with best picture honors (Simonton, 2011).

Movie awards do have some drawbacks as impact criteria. First, like financial performance, counts of awards and nominations are highly skewed. Only a minority of films are even nominated for any award, and a smaller proportion of these actually receive one. Second, the awards and nominations are often influenced by factors that are extraneous to actual cinematic merit. For instance, the larger the number of prior Oscar nods a director receives the higher the probability that he or she will win the award (Pardoe and Simonton, 2008). Third, certain genres are favored over others. Dramas are far more likely to win a best picture Oscar than are comedies. Horror and science fiction are even more disfavored than comedies.

Criteria Correlations

If these three sets of impact all highly intercorrelated, then it would not matter which one was actually selected for study. One might serve as a proxy for all. Better yet, the three sets could be combined into a single composite measure of cinema greatness. Unfortunately, the empirical results yield a more complex picture (Simonton, 2011).

To start with, the correlations between critical evaluations and financial performance are only weakly positive. Some researchers even find zero or negative correlations. Many of the inconsistencies can be attributed to the specific criterion in each category. For instance, although critic evaluations will often correlate negatively with first-weekend gross, they will more often correlate positively with total gross earnings. The early financial success of a film is often heavily influenced by promotion and advertising, whereas its ultimate success is contingent on aesthetic quality, which the critics do a good job assessing. The connection between critical acclaim and box office success is moderated by other factors, too, such as the presence of stars. Moviegoers will often buy tickets to see a star-studded film even if it is panned by the critics.

Financial performance also has an ambivalent relation with movie awards. One complication ensues from the timing of a film's release. If a film comes out toward the end of the calendrical year, then its receiving special recognition can enhance its box office success. But if a film is released early in the year, it may no longer be in the theaters by the time the award ceremonies begin. In that case, the question becomes whether its financial performance might earn it some honors. Another nicety concerns the distinction between nomination and actual award. These are seldom announced at the same time, and this temporal lapse can affect the association. As an example, consumers may go see the movies that have received Oscar nods for best picture, but not go back to see again the film that actually won. In that situation, the nominations but not the awards influenced financial performance. One final complication is that only high-profile recognition bears any relation with financial performance. Few consumers go see a film to enjoy its sound mixing.

In contrast, the correlations between critical evaluations and movie awards are consistently and unambiguously positive. It is rare for a critically acclaimed film not to receive such recognition. Indeed, the correlation would probably be much stronger if it were not for the rather divergent distributions for the two sets of variables. The fine distinctions that critics make at the lower end of the distribution have no repercussions because nominations and awards are almost never allotted to the films at the bottom. Nevertheless, it is essential to point out that not all movie honors are in accord with critical commendation. In particular, critical evaluations correlate most strongly with the awards in the dramatic categories, with direction and writing having the greatest weight. Critics seem to prefer most a great script realized by great direction; the actors and editor merely helping to achieve that realization (Simonton, 2011).

It would seem that of the three sets of criteria, box office is the "odd person out." Critical evaluations and movie awards agree more with each other than either agree with box office indicators. To appreciate the basis for this split, we need to look at the factors that predict each set of impact criteria.

Criteria Predictors

The three sets of impact criteria – critical evaluations, financial performance, and movie awards – can be predicted using a large inventory of variables. Because these predictors have contrasting relations with the criteria, the latter are clearly not assessing the same type of cinematic impact. In fact, it should become evident that there are really two general kinds of film, one concentrating

on artistic creativity and the other on the entertainment business. This discrepancy shows up in the following sets of predictors: budget, screenplay, personnel, and distribution and exhibition.

Budget

Aficionados, consumers, critics, and professionals routinely distinguish films according to their production costs. Big-budget films seem to be most favored by the Hollywood studios while small-budget films are more often produced by independents. The costs of making a film have decided repercussions for all three sets of criteria (Simonton, 2011). In the case of financial performance, the size of the budget correlates strongly with first-weekend earnings and with total domestic gross. In other words, it takes money to make money. As noted earlier, part of this relation is mediated by expenditures on promotion and advertising. The more producers spend the more they are willing to pay for selling the film. Big budgets mean big business for everyone in the industry. Yet, as also mentioned earlier, all of these expenditures on production and promotion do not necessarily result in big profits. On the average, every additional dollar spent on the film brings only about half that amount in return.

By comparison, critics seem disinclined toward big-budget products. Production costs have a negative association with the reviews that a film receives during its theatrical run as well as the reviews received after its video or DVD release. The relation with movie awards is more equivocal. Although costs are positively associated with awards in the visual, technical, and music categories, production costs have no correlation with awards in the categories of best picture, direction, writing, and acting. It seems that money can buy excellence in the secondary aspects of the film experience, but cannot necessarily do so in the primary aspects. Many of the greatest films were actually medium- or even low-budget products. However, because the correlation is zero, there will be instances of big-budget films that obtain awards in the dramatic categories.

Screenplay

From what has been indicated so far, film as art focuses on drama. And the key component of drama is the script or screenplay. The best directors and actors cannot salvage a bad story with implausible characters. Naturally, these scripts vary tremendously not just quality but also in content. So far, research has identified the following seven sets of attributes as being particularly important in separating out the three sets of criteria (Simonton, 2011).

1. *Sequels* are successors to an earlier film, such as the last two parts of the *Godfather* trilogy. Sequels do well in terms of financial performance. At least they gross more, especially in the first weekend. They are not necessarily more profitable, however, because sequels often have higher production costs. There is pressure on the producer to outdo what came before. It is interesting to report that sequels are more prone to receive awards in the technical categories because this implies that the extra money is being spent on bigger and better explosions and car chases. Yet this success has a price because sequels are less likely to win honors for best picture and for the dramatic categories of cinematic achievement. In line with this negative result, sequels receive lower praise from film critics.
2. *Remakes* are similar to sequels in being dependent on an earlier film, only the dependence is even greater. Remakes have very similar consequences as well. On the one hand, they tend to gross more, especially in the first weekend. On the other hand, remakes are less likely to win awards in the major dramatic categories – direction, writing, and acting – and they are more likely to be panned by the critics. Remakes, like sequels, are show business, not artistic expression.
3. *Adaptations* are like sequels and remakes in bearing some link with a previous creative product. Yet the predecessor now comes from a different medium, especially plays and novels. In terms of box office, adaptations from novels are neither better nor worse than average while adaptations from plays have poorer financial performance. As might be expected, adaptations have higher odds of winning awards in the principle categories of cinematic achievement. If the adaptation comes from a classic literary work, the resulting film is also prone to receive recognition for art production, costume design, and makeup. Such visual honors represent the typical “costumer” based on a novel by Charles Dickens or Jane Austin. Given the critical preference for fine art, it should come as no surprise that adaptations are more apt to earn critical acclaim.
4. *True stories* purport to represent real events, albeit with varying degrees of factual accuracy (e.g., “based on a true story”). A special case of true stories is the *biopic* that claims to narrate the life of a real person. Because the scripts of true stories and biopics are often adaptations from nonfiction, they have somewhat similar correlates. They tend to do less well at the box office but score higher in critical reviews, plus earn more awards for best picture and the dramatic and visual clusters.
5. *Genre* is an extremely complex attribute simply because there are so many different varieties that can be combined in almost unlimited ways – like the horror sci-fi comedy. Even so, one genre dominates film scripts, namely, drama. Well over half of mainstream films are dramas of one kind or another. Dramas make for good art, too, for they tend to receive higher critical praise and they have a higher likelihood of winning awards in the principal categories. On the down side, they are less likely to earn recognition in the technical categories, and they earn less at the box office. Film dramas are too serious to make business sense.
6. *MPAA ratings* are determined by the Motion Picture Association of America. They are designed to ensure that films are exhibited before appropriate audiences. For current purposes, the most relevant ratings are R and PG-13. The former indicates “Restricted, children under 17 would not be admitted without an accompanying parent or adult guardian” and the latter “Parental Guidance advised, parents strongly cautioned because some material may be inappropriate for children under 13.” Films rated PG-13 do

the best in the box office, those rated R the worst. Yet R-rated films earn higher critical acclaim and receive more recognition in the dramatic cluster of movie awards – but less recognition in the remaining three clusters. Needless to say, many R-rated products are dramas.

7. *Mature content* indicates serious material unsuited for children or unwelcome by some adults. The most conspicuous types of mature content are highly graphic sex and violence. Although this attribute is partly captured by the MPAA ratings, the latter are too broad to make appropriate distinctions. For instance, an R-rated film might contain no sex or violence, but just profanity, while a PG-13 film might contain some nudity and killing. Consequently, it is of interest to learn the impact of mature content apart from the MPAA ratings. Here the contrast between art and entertainment is quite conspicuous. On the artistic side, both critical acclaim and movie awards in the major categories are positively associated with tense family scenes, controversial topics, and, oddly, smoking – the latter perhaps a sign of a “serious” film product. On the entertainment side, box office gross is positively associated with scary or tense music, frightening or tense scenes, but negatively associated with sex and nudity, profanity, and alcohol or drugs. These financial measures hold for US domestic, UK, and worldwide box office.

Although the preceding variables all have contrasting associations with the three sets of impact criteria, one attribute has been found to be positively correlated with all three, namely runtime. Evidently, the longer the film the more opportunities it has to display the full range of cinematic effects. It then earns more money, gets better reviews, and wins more awards in all categories. Yet film length is also a rather crude indicator of screenplay characteristics.

Personnel

Shakespeare’s plays can be read with pleasure and profit without seeing them on the stage, but screenplays rarely enjoy that expressive autonomy. Instead, the script must be translated to the screen, a translation that demands the direct contributions of cast and crew. The impact of the final cinematic product will also depend on those contributions. Let us start with the cast and then turn to the crew.

The cast consists of the talents in front of the camera, especially those actors in leading roles. The bulk of the empirical studies narrowed their analyses to the impact of the “movie stars” occupying those roles (Simonton, 2011). With respect to critical evaluations, there is some reason to believe that acclaimed films are more likely to feature performances by male and female actors who had previously won Oscars. Moreover, performers who have accumulated previous acting nods are more likely to deliver Oscar-winning performances. Regarding financial criteria, the impact of stars is inconsistent and unstable. Although films with star names on the marquee are likely to gross more, such films are often not cost effective. Because stars earn so much more money, the increase in budget frequently cancels out any gains in box office. One last point is of interest: The impact of male stars exceeds that of female stars. At least this holds for both financial performance and best picture awards.

Research on members of the crew has so far confined attention to producers, directors, writers, and composers (Simonton, 2011):

1. Producers have only been studied with respect to financial performance, but with paradoxical results. On the one hand, producers with prior box office success are more likely to continue that success. On the other hand, the greater the number of prior films produced the lower the odds of an exceptional box office for a current film.
2. A similar paradox happens to directors: prior box office performance predicts positive box office for current films but prior credits predicts negative box office for current films. As a result, the net effect of “star” directors is zero. But when we turn to movie awards, these do tend to be predicted by prior movie awards: Outstanding directors continue to win. Yet with respect to critical acclaim, directors display an inverted-U function of age similar to what is found in other forms of creativity. The films for which a director receives the highest critical praise tend to appear mid-career.
3. While award-winning writers are prone to write additional award-winning films, the findings are less simple for that subset of writers who also direct their own scripts. On the one side, films made by writer-directors tend to be favored by the critics, and on the other side, films written and directed by the same creator tend to do less well than average at the box office. Because Auteurs are often writer-directors, these findings suggest that Auteur theory applies more to film as art than to film as entertainment.
4. Composers appear largely irrelevant to a film’s financial performance. At least box office is unrelated to awards received for best score or best song. In comparison, award-winning compositions are positively associated with best picture honors. The critics are less enamored of film music, especially in the case of songs. One curious finding is that the aesthetic impact of a film composer’s work is largely decoupled from the overall cinematic impact of the film. Sometimes a composer’s best work is found in a lesser film.

All in all, the cast and crew make rather divergent contributions to a film’s cinematic impact. The magnitude and direction of their effects depend on the specific criterion.

Distribution and Exhibition

Until very recently, with the advent of Netflix streaming, a film could not even receive critical evaluations, earn a box office gross, or win movie awards unless it has some theatrical release. This leads to two final variables that are differentially associated with the impact criteria (Simonton, 2011).

First variable is the season of release. Regarding financial performance, it is patent that the big blockbusters are released in the summer months, when children and adolescents are on vacation. In contrast, critically acclaimed films as well as those with the highest odds of winning movie awards are most likely to be released toward the end of the year, during the so-called Christmas season. Interestingly, the worst movies by any standard are usually released early in the year – a dumping off period for films that do not go directly to video.

The second factor is the number of screens on which the film is exhibited opening weekend. Wide-release films not only do better on the first weekend, but also tend to gross more in the end. Yet such films are more likely to receive negative reviews from the critics, who lean toward films that do the art-house circuit, a few screens at a time. Although the number of screens is unrelated to movie awards for best picture and in the dramatic and visual clusters, wide release is positively associated with honors in the technical and music clusters. This pattern suggests that wide release is reserved for entertainment rather than for art.

Discussion

An overall pattern is apparent in the above review: Films can be separated into those devoted to creative art and those dedicated to the entertainment business. The former are inclined to receive critical acclaim and movie awards in the primary categories, whereas the latter are more disposed to do a handsome box office and to earn awards in the secondary categories, such as special visual effects and sound effects editing. The two types of film can also be distinguished with respect to production costs (small vs. big), screenplay (e.g., sequels vs. adaptations, R vs. PG-13 MPAA rating), personnel (e.g., writer-directors), and distribution/exhibition (e.g., summer vs. winter release). Although there are a few variables that cut across the two cinematic types – most notably long runtimes contributed to both art and entertainment – these exceptions are rare. Often the predictors will have opposite signs for the two types.

To consolidate these findings further, it is necessary to discuss some methodological and substantive issues. This discussion can help improve the quality of future research on cinematic creativity.

Methodological Issues

The empirical findings summarized earlier represent the most common results. Nevertheless, it is important to admit that the literature is not always consistent, and sometimes outright contradictory. After subjecting these discrepancies to scrutiny, it becomes clear that they often emerge out of methodological differences. The following four contrasts are the most telling:

1. *Sampling* – Research varies greatly in the criteria used to obtain a sample of films. In the first place, studies might differ in the historical period covered, some taking films from the Golden Age of Hollywood while other studies taking only very recent films. This difference has been shown to affect the outcomes. Even when the periods spanned by the sample are the same, researchers will often employ inconsistent sampling criteria. To illustrate, the films might be defined by (a) a random sample from all released films, (b) films that received at least one nomination for some movie award, (c) those that earned a certain minimum amount at the box office, (d) those that featured at least one movie star, or (e) films that received a certain minimum number of critical reviews. Rendering matters worse, investigators do not always agree on whether to include documentaries, animations, foreign-language films, or even shorts. It is unreasonable to expect the same results to come from samples so different.
2. *Variables* – Because researchers in this area hail from a great diversity of disciplines – among them psychology, sociology, economics, management, marketing, communications, journalism, broadcasting, and statistics – they often approach the subject from rather divergent theoretical perspectives. Consequently, each study will contain a different mix of variables. For instance, marketing researchers are more likely to want to put expenditures on promotion and advertising into their prediction equations. Yet the omission of these expenditures by other investigators can alter the conclusions. For example, much of the relation between budget and gross earnings vanishes once expenses on promotion and advertising are controlled (or “held constant”). Hence the latter provides the most proximate predictor of financial success.
3. *Measurement* – Even if two studies used identical sampling criteria and included the same variables, they might obtain contrasting results because of disagreements on how to best define the key variables. Undoubtedly, the most irksome illustration comes from the concept of the “movie star.” Stars have been defined in terms of (a) best-acting awards, (b) consumer surveys, (c) box office performance, (d) total film credits, (e) investigator subjective assessments, and (f) industry-based identifications. A star by one definition is usually not a star by another definition.
4. *Analysis* – It is still possible for two investigations to concur on sampling, variables, and measurement, but obtain different findings because of divergence in how their respective data sets are analyzed. One investigator might just look at the basic correlation coefficients while another conducts a multiple regression or constructs a structural equation model. Even a single method like multiple regression can get distinguishable results if the analysis is carried out differently (e.g., simultaneous vs. stepwise). Finally, researchers will often differ in how they handle highly skewed distributions. Such divergence is especially crucial with measures of financial performance.

Until some consensus is reached on sampling, variables, measurement, and analysis, it is too optimistic to presume that researchers will come up with identical conclusions.

Substantive Issues

Assuming that the foregoing methodological issues can be resolved, it is hoped that researchers can address a wider range of substantive issues. These can be put into two broad categories.

First, future research must greatly augment the inventory of variables that might contribute to cinematic impact by any of the three criteria. Film is one of the most complex forms of artistic creativity ever devised – perhaps the most complex ever. Although researchers often feel satisfied if they incorporate a few dozen variables into their studies, such satisfaction is quite complacent. Of special importance is a more detailed attention to the screenplay. The published studies to date deal with the most basic features of the screenplay, such as genre, MPAA rating, sequel/remake, and adaptation. Even though there have been attempts to subject screenplays (or synopses) to content analyses, these attempts are clearly exploratory. The analyses come far from capturing the rich complexities of plot, character, and other dramatic components.

Second, further inquiries should also shift the unit of analysis from the film to the filmmakers – the cast and crew engaged in creating the film product. Even if film is a collaborative product, it remains the case that collaborations require collaborators. These collaborators range from creative talents to technical experts, but they all have a responsibility for the final film. There has been some empirical attention devoted to directors, writers, actors, cinematographers, and composers, but these inquiries are rather sporadic and scattered in approach. At present, the literature lacks findings that must be considered essential. As an example, although we know how the personality of artists differs from the personality of scientists, and even how scientists practicing in different disciplines vary in their dispositional makeup, we know nothing about the distinctive personality profiles of producers, directors, writers, actors, and composers – even less the rest of the core crew.

In time, we may come to comprehend cinematic creativity in all of its manifestations. Someway, such scientific knowledge might even enable producers to improve their product.

Glossary

Adaptive Flexibility Abandoning conventional problem solving methods that have become unworkable and thinking of original solutions

Androgyny Persons who have higher than average male and female elements in their personalities

Attitude A lasting tendency or acquired predisposition to evaluate a person, event or situation in a certain way and acting accordingly

Cognition Processes of knowing, including attending, remembering, and reasoning along with conceptualization, judgment, and information processing

Divergent thinking An aspect of creativity characterized by an ability to produce unusual, but appropriate, responses to standard questions

Functional fixity The belief that objects have only one purpose

Spontaneous flexibility Producing a diversity of ideas in a relatively unrestricted situation

Flexibility has a relationship with the act of creativity in several ways. It can be manifested in cognition, which facilitates creative problem solving. Individuals can be flexible in their personalities and attitudes as well, and attitudinal flexibility may, in turn, lead to tolerance and adaptability.

Flexibility as a kind of adaptability reflects a capacity for change. People with this capacity demonstrate a change in the meaning, interpretation, or use of information; a change in the understanding of a task; a change of strategy in doing the task or a change in the direction of thinking, which may mean a new interpretation of the goal. Flexibility as a personality trait allows one to see the whole of the situation. It allows an individual to see all the components of a problem and not just one of the parts. It enables discernment of the parameters and boundaries of problems, and it often enables changing the problem itself. This is because the flexible person is capable of redefining the problem and adapting to the demands of a changing world.

Flexibility in Divergent Thinking

The relationship between cognitive processes and creativity is well-established. Many authors have detailed how cognitive processes play roles in the act of creativity. In all of these approaches, flexibility is underlined and presented as a substantial condition for creativity and thus creative people are flexible (Guilford, 1968; Runco, 1991).

Flexibility is a concept that hinges on the relationship between creativity and adaptability. Flexibility enables people to interpret the world from different perspectives and adapt to change, which may contribute to the ability to make associations and a greater openness. Flexible individuals usually have alternatives and diverse solutions when solving problems. Thus, they more likely reach solutions and are less likely to have distress and frustration. Inflexible individuals, on the other hand, usually follow routines and are stuck with a solution used earlier.

Flexibility is an important aspect of the cognitive process. It has been evidenced that divergent thinking is a very useful estimate of creative thinking potential. Tests derived from the well-known divergent thinking model assess creative thinking potential by measuring four dimensions: originality, fluency, flexibility, and elaboration. Thus, creative individuals are expected to demonstrate fluency, greater originality, more flexibility and elaboration. Fluency is about the generation of a quantity of ideas. It is measured by presenting very simple tasks (e.g., list all the things you can think of that are hot and solid), and the quantity of output gives the

fluency scores. Originality on divergent thinking tests has to do with looking beyond obvious solutions, novelty, and generating novel ideas and responses. The more the statistical infrequency of responses, the more the originality. It is measured by the production of unusual, remote, far-fetched, clever and breakthrough solutions. Elaboration is the ability to expand on an idea and enlarge it with details. Unlike fluency, it refers to the details within each idea. Finally, flexibility is manifested when the responses or solutions move from one ideational category or theme to another. The more the category of ideas or ideological shift in thinking, the more the flexibility.

The divergent thinking model has been criticized because of the moderate predictive validity of divergent thinking tests and the ambiguous associations with creativity occurring in the natural environment. It is obvious that divergent thinking and creativity are separate constructs; however, divergent thinking tests provide very useful estimates of the potential for creative thought. Recent research indicates that divergent thinking tests produce the most impressive validities when flexibility is incorporated into the assessment and prediction (Runco, 1986).

Types of Flexibility

Flexibility has two types: spontaneous flexibility and adaptive flexibility (Guilford, 1968). The former is termed spontaneous because it can appear as a natural tendency or spontaneous preference for change for intrinsic reasons. It is the ability to generate diverse solutions to a problem when there is no external pressure to be flexible (Thurston and Runco, 1999). In some divergent thinking tasks to measure spontaneous flexibility, an examinee may be asked to list as many ideas as possible regarding the use of a common object such as scissors without being given the suggestion to be flexible on tests. The score for ideational fluency is the total number of uses listed and the test can also be scored on the number of times the category of use is changed. For example, the responses of “cut hair”, cut paper, cut fabric” does not change the class of use. On the other hand, the response of “make the letter X, make a paperweight, use as a screwdriver, use as a draftsman compass,” etc., changes class with each new response. The examinee who has the tendency to change conceptual categories easily and provides more categories demonstrates much more spontaneous flexibility.

The other type of flexibility is called adaptive flexibility or redefinition. It can appear under the pressure to adopt to a challenging external environment. It is the ability to adopt new strategies to solve a problem when old methods do not work, or to redefine the problem in order to find an original solution. It occurs in relatively difficult tasks. Adaptive flexibility can be measured by designing tests to identify the ability to see ordinary things in the environment from a different perspective, and make connections between distant points (Georgsdottir and Getz, 2004). An examinee must make some kind of modification either in the interpretation of the task, in strategy or approach or in possible solutions. There should be substantially modified responses that represent a transformation to adaptive flexibility. Adaptive flexibility in response to environmental constraints can introduce creative outcomes. For example, approaching problems in new ways and shifting perspectives on a problem can facilitate creative solutions and creative insights.

Flexibility in Insight Problems

Wallas suggested that the creative process includes four stages: preparation, incubation, illumination, and verification. The third stage, illumination is also known as insight. It is best known because it appears with an a-ha experience. Schilling (2005) defined insight as making unexpected connections between disparate mental representations. Insight usually leads to one solution. When we have a problem, a solution or idea pops into our minds. It is sudden or, at least, feels that way.

In creative problem solving, insight problems are frequently used and require flexibility. Among insight problems presented by Schilling (2005), nine dots and two-string are well known. In the nine-dot problem, for example, nine dots are presented (see Fig. 1), and the examinee is asked to connect all nine dots with four straight lines without lifting pen or pencil from the paper until the dots are connected.

Most people assume that a boundary is imposed by the eight dots making up the perimeter of Fig. 1. Although no such boundary or constraint is given in the direction, people usually stay within that self-imposed perimeter while attempting to solve the problem. This indicates that they may be generating assumptions that limit their thinking. This also says something about how we structure our perceptions toward Gestalten or have an inclination to complete figures. What is most relevant here is what the experts say about flexibility –or the lack thereof. When the examinee sticks with one approach to a problem, it shows low flexibility. People trying to draw various lines, but all within the perimeter, experience functional fixity. Those with flexible thinking, on the other hand, will try varied approaches. They may try lines within the perimeter at first; however, the next attempt would reflect a different approach with lines outside of the perimeter, which is the way to find solutions to the nine-dot problem (see Fig. 1).

Functional fixity restricts people from having diverse approaches to problems because of preoccupation with previous experiences and conventional thinking. Extensive knowledge in a domain can be helpful but does not guarantee creative ideas. In fact, it may hinder flexibility and the creation of diverse ideas or solutions. Thus, it can be described as a cost of expertise in some cases. It is clear that flexibility is crucial to insight in problems, as well as divergent thinking tasks.

Figure 1 Conceptual blocks in the nine-dot problem.

Flexibility as Personality Trait

The relationship between personality and creativity has been studied extensively. Evidence reveals that certain personality traits are closely involved in the creative process. However, ambiguity still exists about personality as the direct and primary cause of creativity. Research indicates that various traits have a role in enhancing creativity. These traits include flexibility, risk taking, delay of gratification, preference for disorder, stimulus freedom, functional freedom and psychological androgyny. A meta-analysis by [Feist \(1998\)](#) indicated that creative individuals are more autonomous, hostile, dominant, impulsive, confident, extroverted, and open to new experiences. Other traits commonly associated with creativity include tolerance for ambiguity, independent judgment, ambition, perseverance, nonconformity, self-confidence, motivation, and initiative.

Flexibility can manifest itself as an attitude, which may be described as “a lasting tendency or acquired predisposition to evaluate a person, event or situation in a certain way and act accordingly” ([Vander Zanden, 1990](#), p. 19). When a person has a creative attitude, he or she has an inclination to think and act with a certain degree of flexibility and use unconventional methods while trying to solve a problem. Realizing all the components of a problem, and being aware not only of his or her own point of view, but also those of others can help produce creative solutions. Modifying strategies and lines of action to recognize and solve a problem is an indicator of the creative attitude. This creative attitude may emerge in various field of knowledge including artistic, scientific, cultural, and even in everyday life. Therefore, flexibility supports adaptability by providing options.

Frank Barron found that writers as a class are significantly more flexible than most people, and that creative writers who have achieved renown are 84% more flexible than the general population. On average, artists and scientists are more flexible than non-artists and non-scientists. Maintaining a certain direction for a long period of time, when the target is not always visible or contains many uncertainties, requires an extraordinary adaptive ability and a particular coping strategy. At this point, being flexible helps by changing one’s strategy in solving a problem or doing a task, changing the direction of thinking or even changing the problem itself. [MacKinnon \(1978\)](#) found that creative architects, more often than those less creative, reported turning to another activity when seriously blocked in a task and returning to it later when refreshed. Less creative architects, on the other hand, more often reported working stubbornly on a problem when blocked in their attempts at a solution.

Flexibility and Development

Flexibility may be tied to developmental experiences that enhance creativity. For example, evidence has revealed a reciprocal relationship between playfulness and creativity. Playfulness is one of the critical human traits of creative personalities. It is obvious that many scientists, artists, and composers, known for their creativity, are also playful ([Bateson, 2015](#)). Playfulness can be described as approaching situations in an exploratory manner and seeing the lighter side of a challenge with a sense of humor (see [Play](#)).

Playfulness, as associated with a positive mood, can stimulate creativity. Furthermore, different aspects of creativity may be affected by playfulness, or a positive mood in general, in different ways. For instance, playfulness enhances flexible thinking along with originality and fluency. Playfulness or the predisposition to engage in symbolic play has been associated with a high level of fluency in children. Playful behavior or playful thought helps generate new approaches to problems. The more playful children are, the more they are creative. Based on studies of kindergartners, high school students, and adults, it appears that playfulness and the flexibility it supports become part of an individual’s personality and are an essential ingredient in creative thought ([Alcock, 2007](#)).

Play as an important form of behavior facilitates creativity during the lifetime of each individual. It is evidenced that children’s play experience and their subsequent creativity are clearly intertwined. For example, the children with more opportunities to play achieve significantly higher scores on creativity. Engaging in extensive imaginary play during childhood has relevance to the creativity of those who are honored for their creative work as adults ([Root-Bernstein and Root-Bernstein, 2006](#)). Children who have spent time playing tend to be more creative on tasks they do immediately afterward than those who go directly from one task to another.

Flexibility is also related to sex role identification, which is learned first in families and then reinforced by the social environment and culture. Sex roles are a substantial part of an individual's belief system, whether or not he or she is creative. Apart from traditional male and female sex roles, a new sex role has been identified with has implications for creative thinking. Known as psychological androgyny, it refers to a kind of eclectic combination of both feminine and masculine behaviors. These people have above average male and female elements in their personalities. Androgyny is not a midpoint between the traditional sex roles. Rather, it includes elements from each of the two poles of masculinity and femininity, thereby becoming a higher level of sex role identification (Bem, 1974).

Sandra Bem (1986) illustrated the relationship between androgyny and creativity. Highly conventional people usually shy away from androgynous behaviors and have rigid sex roles. People with such rigid sex roles have conflicts accompanied by stress, which causes a great expenditure of energy. Bem outlined that having a traditional sex role as a form of rigidity may be detrimental to personality. If an individual is too strongly socialized to act in terms of a strict sex role, his or her creativity is likely to be inhibited. She concluded that as androgynous individuals look for a truly appropriate course of action without sticking rigidly with a role, they are far more functional. Such functionality fosters flexibility and creativity, accordingly. Her research concluded that androgynous individuals' scores on a measure of cognitive flexibility are higher than those who are feminine or undifferentiated. This is also supported by Csikszentmihalyi's (1996) findings about the paradoxical balance of masculinity and femininity. Importantly, the psychologically androgynous person is likely to be psychologically healthy, as well as creative.

Another developmental issue involves open-mindedness, a personality trait generally associated with flexibility. Open-mindedness has been described theoretically and empirically as a general disposition for creativity. It has been frequently evidenced to be positively related to divergent thinking. It is a strong predictor of divergent thinking, everyday creativity, and creative achievement. Those who are open minded have an ability to receive new information without prejudice. They tend to be imaginative and curious; thus, it is not surprising that open people are more creative. Creative people, on the other hand, tend to treat the new and different as a challenge rather than a threat. It seems that openness is the breadth, originality, and complexity of an individual's mental and experiential life. The mind open to new experiences and ideas more likely attains an insightful understanding, flexible thinking, and creative outputs.

Open-mindedness emerges in childhood and develops as a trait through adulthood. Parenting style seems to play a substantial role in the development of open-mindedness. Children encouraged by their parents to be adventurousness, risk takers, and assertive develop flexible personalities. Growing up in diverse cultures or experiencing diversity in different aspects of life may also help people to be open minded and, accordingly, cultivate their flexibility. Open-minded individuals with flexible personalities have a tendency to be less rigid, less neurotic, and less anxious than most.

Summary

Flexibility is an important dimension of the creative cognitive process as seen in the divergent thinking model. It has been evidenced that creativity needs flexibility, and creative people are generally flexible and adaptable. It is clear that flexibility is useful for insight into problems, as well as in divergent tasks.

Flexibility is needed for real world problem solving. When faced with a problem or issue, having diverse approaches or solutions rather than sticking with only one solution (fixity) is an obvious benefit of flexible thinking. Many real-life problems require people to go beyond conventional ways of thinking and break standard patterns. For example, when there are not enough ingredients to make dinner, when you have no money to watch a game, or when you need to convince a stubborn friend, you need to diverge from the common ways of thinking and vary your approach for a solution. This is possible through flexible thinking.

Flexibility as a personality trait has a role in promoting creativity. Flexible personalities are mostly open-minded. Besides, flexibility as an attitude allows people to become aware of all the components of a problem, and not just stick on one of the parts. Those with flexible personalities tend to be less rigid, less neurotic, and less anxious than most.

Flexibility is also related to developmental experience. Playfulness as a part of an individual's personality fosters flexibility and creative thinking, accordingly. Psychological androgyny as a type of sex role identification cultivates flexibility and the search for the truly appropriate course of action; therefore, it fosters creativity and allows an individual to be more functional.

Flow as Optimal Experience

It is what the sailor holding a tight course feels when the wind whips through her hair, when the boat lunges through the waves like a colt – sails, hull, wind, and the sea humming a harmony that vibrates in the sailor's veins. It is what a painter feels when the colors on the canvas begin to set up a magnetic tension with each other, and a new *thing*, a living form, takes shape in front of the astonished creator. Or it is the feeling a father has when his child for the first time responds to his smile.

Csikszentmihalyi (2008, p. 3)

The concept of flow which Csikszentmihalyi vividly describes above was introduced into psychology in 1975 culminating in his seminal work *Flow: The psychology of optimal experience* (Csikszentmihalyi, 2008). In his study of high-performing individuals from a range of domains, Csikszentmihalyi found flow in sports activities, games, rituals, professional activities and in artistic creations, when he asked his interview partners to describe the optimal experience, which made them feel happy and kept them motivated. Their optimal experience included a sense of effortless action, as if nothing else seemed to matter, and the experience itself was the whole. In such moments, thoughts, feelings, wishes, and action are in concert (Nakamura and Csikszentmihalyi, 2011). Put in general and abstract terms, being in flow represents a duality of performing and feeling at a peak level.

The flow experience is often paraphrased in everyday language as 'being in the zone', 'being on the ball', 'being in the groove', 'being in ecstasy', 'being lost in the moment', 'aesthetic rapture' or 'a magic moment'. This optimal experience is not static but on the move from one moment to the next, in which people feel no distinction between self and environment. In flow, past, present, and future seem to conflate.

Flow is an experience of total engagement in an activity and refers to a blissful state of intensified consciousness that occurs during an optimal experience. In flow, people feel simultaneously efficient, motivated, and happy (Moneta and Csikszentmihalyi, 1996). They experience a sense of control over their own actions and operate at full capacity. This optimal experience occurs when cognitive, physiological and affective aspects are brought together and a person's mind and/or body are stretched to the limit (Csikszentmihalyi, 2008).

Flow is rarely perceived by people during passive episodes or moments. It occurs, for example, when people are doing their favorite activities, at a level that is challenging, but not overwhelming. Flow occurs at varying levels of intensity and ranges from microflow in daily activities to intense flow experiences, the latter of which are usually experienced less frequently in life. Flow experience requires activity and the level of flow experience is dependent on how much the activity is intrinsically motivating and rewarding in and of itself rather than its outcome. However, flow can be experienced in an activity, which is not intrinsically motivated at first. A person could be assigned to a task and become completely involved in this activity so that the initially extrinsically motivated behavior could become intrinsic during its performance.

Since the 1970s, flow has developed into an interdisciplinary research field with published overviews in fields including psychology, sociology, sports science, management, and organization studies. The concept of flow is a significant starting point for the more recent discipline of positive psychology. It is important to note that flow is not only a meaningful research concept, but also a phenomenon which can easily be comprehended by most people by relating it to their own experiences.

From the beginning, flow and creativity have been closely intertwined, as exemplified in Csikszentmihalyi's publication from 1996 *Creativity: The psychology of discovery and invention*, in which he studied exceptional cases of individual creative work (Csikszentmihalyi, 2013). As creativity is an essential factor in all human progress and flow is a significant driving force of creativity, their close relationship makes the study of creative flow important. In contrast to flow in general, creative flow involves the search for discovery and novelty.

In a study about flow in work and leisure, Csikszentmihalyi and LeFevre (1989) found that creativity was self-perceived at higher levels in flow than in non-flow, and that above-average levels of creativity were reported during work flow. However, the exact relationship between flow and creativity is still under investigation, especially the question of whether flow is a precursor, a mediator or a parallel phenomenon to creativity and to what extent creative flow is related to creative outcomes.

Components of Flow

Although it is generally agreed that flow is a higher order construct, research varies concerning which components contribute to flow (Nakamura and Csikszentmihalyi, 2011). Based on an analysis of several interviews, Csikszentmihalyi's (2008) findings indicated that individual, social and cultural differences have very little impact on the flow experience, suggesting that the phenomenon in terms of how it is experienced can be regarded as nearly universal across socio-cultural settings. He came to the conclusion that the flow experience consists of the following eight components, 1 to 3 being pre-requisites or proximal for flow, 4 to 8 being elements of being in flow:

1. Balance between the level of skills and challenges: The fundamental component to reach flow in a specific activity is a bundle of opportunities that requires fitting skills. For those individuals who do not have the appropriate skills, the activity is not challenging.
2. Clear goal in the activity: There has to be a defined purpose and a precise idea of what to do next. Although the activity advances towards the final goal, the activity is driven by the realization of the next small goal.
3. Immediate feedback: While engaged in the activity, immediate feedback is necessary to make adjustments in order to reach the goal. Feedback often happens in real time without it being necessary to stop the activity.
4. A high degree of concentration: In flow, people's mental awareness is reduced to performing the activity, to the point where they may forget about general physical and mental needs. People in flow maintain focus with all their attentional resources on the relevant aspects of the goal and exclude distractions. A merging of action and awareness is essential to experiencing flow, such that any reflective thoughts that detach the person's awareness from the activity, for example, asking "How am I doing here?", will disrupt their flow.
5. A loss of self-consciousness: During a flow experience, people forget themselves and are so involved in the activity that they require most of their mental resources. People lose their worries how they appear to others.
6. A loss of sense of time: People forget the time during the flow state. Time seems to pass really fast when people are performing activities in which they are highly engaged.
7. A sense of control: In flow, people do not worry about a possible loss of control and even failure are taken into account. All external elements are less relevant because people are deeply engaged in the activity and can in general deal with the situation.
8. Autotelic experience: Flow is a happy experience which is intrinsically rewarding whereby the reward is directly connected with the activity. People are motivated by a strong wish to do the activity and reach the goal.

The flow experience is a function of challenges and skills in a specific activity. Therefore, the flow experience is dependent on the task, the situation in which it is experienced and the person's specific skill level (Nakamura and Csikszentmihalyi, 2011). The fundamental idea that flow is only experienced, when challenges posed and accessible skills are adequately matched and above average, is profoundly illustrated in Fig. 1. Boredom occurs where the challenges do not match the skills, and a region of anxiety exists where challenges exceed the skills. A balance of below average challenges and skills does not lead to flow but to an experience, which could be described as apathy. Its dependence on skills and challenges suggests that flow experience varies during an activity and between activities and, thus, should not be viewed as a state of high temporal stability. Moneta and Csikszentmihalyi (1996) noted that flow does not impose a maximum or equilibrium point to be perceived by the individual and that flow is fleeting and usually increasing over the course of an activity.

The intensity of the components of flow is perceived subjectively and, therefore, individual flow experience is highly personal. Correspondingly, the range of possible intensities of flow differs between people and situations. In addition, the environment and how it fluctuates influence the intensity of the components of flow, therefore, the flow experience should be regarded as a compound or holistic sensation (Nakamura and Csikszentmihalyi, 2011). Flow's interdependence with the environment is a key characteristic shared with creativity.

Empirical evidence showed that the components of flow positively correlate during the flow experience, but their strength and importance can vary. In empirical studies, Moneta and Csikszentmihalyi (1996) as well as Primus and Sonnenburg (2018) confirmed that four indicators, namely concentration, happiness, wish to do the activity and involvement adequately reflected individual flow feeling. Both studies confirmed that the four indicators were positively correlated to the individual flow corridor, reflected by balance and depth of challenges and skills.

Group Flow

The concept of individual flow has subsequently been expanded to the group level. While individual flow describes a state of consciousness within a human being, group flow is an emergent phenomenon of the group as a collective property. It is important

Figure 1 The flow corridor based on Csikszentmihalyi (2008).

to note that in flow the group has autonomy and authority during the group activity. In group flow, every individual contribution seems to come naturally. Each member feels as if all group members are able to anticipate what their fellow agents will do before they even do it.

The possibility for high group flow is increased when the level to which the group has to attain a collective goal is matched by a number of pre-existing structures shared and used by the members like an overall outline, a shared knowledge repository, clearly defined roles, and a common agreement on the conventions (Sawyer, 2003). The following seven components are indicators of group flow:

1. Constant communication: During the group flow experience, all members are always talking and interacting with each other.
2. Close listening: In group flow, no member plans ahead what is to be said so that each contribution is a genuinely unplanned response to what has just been said.
3. Blending egos: Each member has the possibility to contribute to the group flow. At the end, no one can remember who contributed what to the group flow.
4. Equal participation: To reach a peak performance, each member participates equally which requires in general that everyone has a similar level of expertise and authority. However, the expertise should not be too familiar to enable unexpected connections that result in new ideas.
5. Complete concentration: The group is fully engaged in the task with all their resources and without external distractions.
6. Moving the activity forward: In group flow, each member builds on the ideas by the others and elaborates these ideas further.
7. Importance of the activity for each group member: Even if the relevance of the task emerges during the group activity, all members need an intrinsic motivation and a wish to do the activity.

As a result, groups in flow are in “interactional synchrony” (Sawyer, 2003, p. 43), which can be described in everyday language as having ‘good chemistry’ between the group members during the activity. Groups attain and keep the flow at a peak level by staying in interactional synchrony, which pianist Franklin Gordon described: “Every musician wants to be locked in that groove where you can’t escape the tempo. You’re locked in so comfortable that there’s no way you can break outside of it ... It doesn’t happen to groups every single night ... But at some point when the band is playing and everyone gets locked in together, it’s special for the musicians and for the aware, conscientious listener. These are the magical moments, the best moments in jazz” (Berliner, 1994, p. 388). Fig. 2 describes how people get locked in together during a group activity. It has to be emphasized that no two-dimensional figure can adequately illustrate the complexity of real-time interactional synchrony. This figure simply illustrates the process by which group members can get involved into the group flow during the activity.

The horizontal axis, interactional time, represents the permanently changing nature of $E(t)$ which is the group emergent active for a specific flow time. Each individual act during the activity is dependent on several interactional factors, which is illustrated by the example of Agent(1). The emergent $E(1)$, which is the shared property of the whole group at a specific moment in time, affects Agent(1) in the form of linguistic prerequisites, which inspires Agent(1) to develop something new which flows into the interaction process as a linguistic consequence for the other group members. The group itself decides during the flow experience what portion of the linguistic consequence leads to $E(2)$, which is then the new group emergent influencing all group members (in this example $A(2)$) to develop something new.

Sawyer (2003) described the emergent $E(t)$ which changes all the time during the group activity as follows: “The emergent is structured but ephemeral, changes with each performance act ... It is an emergent social fact; it is not determined by any single

Figure 2 Group flow during the activity based on Sawyer (2003).

performer, and only partially constrained by the genre definition. For the interaction to continue as an intersubjective shared activity, the performers must work together in creating the emergent" (p. 87). Members in highly interdependent groups serve as agents of flow for each other and, therefore, group flow is perceived as more enjoyable than individual flow.

While individual flow has been comprehensively studied, the empirical analysis of group flow and, in particular, the interrelation between individual and group flow during a creative activity is just beginning. A positive correlation between individual and group flow can be expected such that when a group is in flow, it is highly likely that its members experience individual flow. In fact, Primus and Sonnenburg (2018) found empirical support that group flow is associated with the individual flow of the group members in a partial least squares (PLS) analysis of experience data from Design Thinking teams. Their results indicated that group flow is positively correlated with the individual flow corridor experience, as well as with the construct of individual flow feeling, reflected by concentration, involvement, happiness and wish to do the activity.

Measurements of Flow

Although research strongly agrees on the definition of flow itself, there is a dispute concerning the measurement of flow. Several self-report tools have been designed to approach this inherently unstable and subjective experience whereby the dominant research methods in literature are interviews and questionnaires.

The original concept of flow emerged out of in-depth qualitative interviews about the nature of the experience, when a specific activity is going well. Interviews provide holistic insights of the flow state in real-life context. In the beginning of flow research, interviews were an important tool to identify the components and dynamics of flow as well as to set the ground for wider based quantitative assessments. Interviews showed that people in all accounts of life felt a flow peak when they were being the most creative. Interview studies are still used to examine flow experience.

First approaches to measure flow with questionnaires started with paper-and-pencil tests. The aim of using questionnaires was to measure the occurrence of previously identified components of flow across individuals and contexts. The paper-and-pencil tests, which today are predominantly web-based, present respondents with several passages describing the flow experience and ask them whether they have had the experience, how often and in what context (Nakamura and Csikszentmihalyi, 2011).

Csikszentmihalyi (2008) developed, applied and validated a novel method to continue his research on everyday flow experience. This approach is based on the experience sampling method (ESM), in which individuals are equipped with a pager that prompts them to complete a questionnaire at several random times throughout the day. Participants answer a set of questions to describe the moment at which they were signaled, about what they were doing and how they felt. The ESM allows intrapersonal and interpersonal comparisons of the flow experience across times and various accounts in life. Unlike interviews and paper-and-pencil tests, the ESM focused not only on the original components of flow experience, but also on other cognitive, emotional, and motivational states, which led to refinements of the components and dynamics to build a systematic flow concept.

Interview and questionnaire approaches are limited by a potential disturbance of the flow state through interruption or by reliance on retrospective reconstruction of the flow experience. This criticism has some truth, but it does not mean that the measurement of flow using interviews or questionnaires is not valid. Even if a respondent is out of flow, she or he can still remember what

she or he has done and felt before. This situation can be compared with a dream. When you wake up, you stop dreaming, but you can still remember content and feelings of the dream and report them.

In recent years, experimental designs with controlled variations of test conditions have played an important role in gaining a deeper understanding of changes in the flow experience during an activity (Moller et al., 2010). For example, games were used to observe, control, induce and vary flow in lab settings. In a one-day experiment, Primus and Sonnenburg (2018) compared the intensity of the flow experience at the individual and group level across different Design Thinking activities and different test groups. EEG as a biometric measurement of the affective states of people gained methodological significance as a way to investigate the relationship between brain waves and the flow experience (Wanga and Hsu, 2014).

Directions in Flow Research

Flow has been developed into a robust concept for research and theorizing. Although it is regarded as a well-founded concept, the investigation of flow together with components related to the interaction of humans and the environment still shapes or adds new components without completely changing the basic understanding. The flow experience is almost identical across lines of culture, class, gender, and age as well as across different kinds of activities. The possibility to experience flow seems to be nearly universal but people vary widely in the frequency and intensity of the reported flow experience.

Classical domains of flow research are science, music, art, dance, writing and religious settings. Further important domains are sports, learning in educational settings, therapeutic settings, game-based learning as well as areas of work. The majority of flow research has focused on activities with clear goals and standards of success which can be monitored and easily regulated. It is noteworthy that some studies approach the negative effects of flow like addiction when exercising or playing video games as well as impaired risk perception and risky behavior (Schüler, 2012). Across domains, the following dimensions are of particular importance:

- Periods and patterns: Flow occurs more often in work than in leisure as work is more related to challenging activities which promote personal growth as well as a successful and fulfilled life. In contrast, the intensity of flow is higher during leisure activities and the level of flow tends to increase at the end of the day and is higher during the weekends. In the relationship between work and leisure, Csikszentmihalyi and LeFevre (1989) identified a paradox that people have more positive flow feelings at work, but also a higher wish to do something else.
- Context and resources: The flow experience is strongly influenced by situational characteristics, which are even more important for flow than personal characteristics or preferences (Fullagar and Kelloway, 2009). Especially autonomy during the activity is a significant predictor for flow. In an educational setting, Bakker (2005) figured out that job resources like autonomy as well as performance feedback, social support and supervisory coaching had a positive influence on the balance between challenges and skills and were positively related to the flow experience of teachers. In addition, flow passed from teachers to their students which illustrates the fluid transition from the psychological to the social dimension of flow.
- Individual attitudes: The need for achievement guides the experience in the flow corridor, even more, a strong need for achievement facilitates reaching higher levels in the flow corridor. When perceiving high challenge and high skill, employees with a strong need for achievement show greater positive mood, intrinsic task interest and greater spontaneity. A positive or spiritual attitude towards life has a positive impact on flow. Kauanui et al. (2010) found out that spiritually connected entrepreneurs experience flow more frequently and provide more likely a creative and playful work environment.

A more recent research direction focuses on the promotion of flow. The goal is not to directly promote the flow experience, but to shape activity structures and environments as well as assist people so that flow is fostered. According to Csikszentmihalyi (2013), it is challenging to make flow happen, but it is possible to learn how to get a mental attitude to approach flow.

With appropriate training, people can develop techniques to reach and stay in flow. For example, a level of daily training is necessary for musicians to be prepared for flow during the performance. On the empirical front, Primus and Sonnenburg (2018) showed that Lego-based activities can be used as a warm-up technique to foster the creative flow on an individual and group level. In particular, athletes have developed warm-up rituals. Here is one described by grand slam tennis champion Rafael Nadal: "Forty-five minutes before facing Federer I began the last phase of my pre-game ritual. I took a cold shower. Freezing cold water. I do this before every match. It's the point before the point of no return. Under the cold shower I enter a new space in which I feel my power and resilience grow. I'm a different man when I emerge. I'm activated. I'm in 'the flow', as sports psychologists describe a state of alert concentration in which the body moves by pure instinct, like a fish in a current. Nothing else exists but the battle ahead. ... I put on my earphones and listened to music. It sharpens that sense of flow, removes me further from my surroundings." (Nadal and Carlin, 2011, pp. 11–12)

Gaps in Flow Research

Although the concept of flow has developed into a hot topic in research and practice, the quite narrow analytical perspective does not help to evaluate flow in its essence. More research is required to analyze the flow experience from a holistic and complex

perspective that sheds light on flow as a dynamic body-mind-construct in interplay with its environment. In addition, it is necessary to integrate and differentiate the state of flow regarding other positive states like mindfulness, meditation or peak performance.

The flow experience fosters individual and group creativity but much more theoretical and empirical work on the relationship between being in flow and (the process of) engaging in a creative activity is necessary to explain the relationship between these constructs. In comparison to other kinds of flow, creative flow is more defined by unclear goals, uncertain feedback and the possibility of surprise.

Empirical research should investigate individual and group flow over time, especially the changes of flow levels during a creative activity. Although flow has a tendency to be unstable, researchers need to understand more about the maintenance and increase of flow in a specific situation. In particular, the link between flow levels during a creative activity, the creative process and the creative outcome have not been sufficiently defined. In this context, it would be useful to study the impact of breaks and fatigue as well as warm-ups and incubation during creative activities.

In addition, future studies should focus more on the creative process itself, as flow may happen anywhere in the stages of the creative process. Individual or group flow may follow after a period of hard work, during incubation, parallel to an insight or in an elaboration of the idea. Research should also include an objective assessment of the creative performance in addition to self-report measures and use more experimental settings in order to control external influences and to examine the flow experience during and directly after it happens. Although it is difficult to inspire flow under controlled conditions, neuroscience research may also provide valuable information regarding flow states.

Glossary

Alpha Press refers to environmental pressures that have an impact on behavior independent of the individual's interpretation of them.

Beta Press refers to environmental pressures that have an impact on behavior, if the individual perceives and assigns meaning to them.

Five As is an abbreviation for Actor, Action, Artifact, Audience, and Affordance, a re-organized framework for the study of creativity development

Four Ps is an abbreviation for Person, Process, Press (or place), and Product, a conceptual framework for the study of creativity.

Persuasion refers to methods or approaches that creative individuals use to create products that change the way that people think.

Potential refers to the latent capacity of something such as creativity to manifest itself.

Introduction

There are many different approaches to understanding creativity. For the past five decades scholars from various domains such as education, engineering, music, art, and entrepreneurship research have considered creativity an important aspect of their discipline. Creativity, which may represent the most fundamental human capacity, is impossible to define with a few simple words. The complex aspects of creativity have led numerous scholars to build up comprehensive frameworks that (a) describe what creativity is, (b) explain how creativity can be developed, (c) discern creativity levels, and (d) clarify why some ideas or products are more creative than others. In 1961, Mel Rhodes published *An Analysis of Creativity*, which is still widely cited by writers who attempt to define the concept of creativity or to articulate the meaning of creativity and its development. In this review, Rhodes' Four Ps of creativity will be explored in detail along with other frameworks based on the Four Ps such as Runco's Hierarchical Theory of Creativity (2007, 2008) and Glăveanu's 5 A's framework (2013).

The Four Ps

When he published his classic article in 1961, Rhodes had collected over forty definitions of creativity in order to map out a concept of creativity. He analyzed his findings on creativity by using the metaphor of a "prism." When light passes through a prism, it presents a rainbow of colors. Like sunlight, when creativity is viewed through the prism of analysis, it will show four different strands which are *Person*, *Process*, *Press*, and *Product*. Rhodes called them the four P's of creativity. He also stated that "Each strand has unique identity academically, but only in unity do the four strands operate functionally." (Rhodes, 1961, p.307). Each of the Four Ps represents a unique perspective on creativity, and the four Ps play compete a concept of creativity that is useful. Each strand might be stressed a bit differently in diverse endeavors; that is, Rhodes' definition has the flexibility to be functional across academic domains.

[☆] *Change History*: April 2019. Daehyun Kim updated the text throughout the article.

This article is an update of M.A. Runco, D. Kim, The Four Ps of Creativity: Person, Product, Process, and Press, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 534–537.

Person and Personality

Rhodes defines *Person* as the information about “personality, intellect, temperament, physique, traits, habits, attitudes, self-concept, value systems, defense mechanisms, and behavior” (Rhodes, 1961, p. 307). It is a common perspective to think that creative individuals have similar personality profiles supporting their creative behaviors. Researchers have tried to identify the core characteristics of creative people, so that a general profile of a creative personality might be used to enhance the diverse domains. Creativity has been associated with openness to experience, robust imagination, intrinsic motivation, divergent thinking, nonconformity, and risk-taking. Of course, these are identified as tendencies. That is, it is not guaranteed that if a person shows these traits he or she will be a creative person. Additionally, it is not guaranteed that if a creative person expresses some creative traits that he or she will continue to demonstrate creativity. In fact, if a person shares some features of the creative profile it means that he or she may have creative potential. That potential could bloom when the person is in the right environment where he or she is able to develop and perform. In other words, there are personality attributes that creative individuals share and those attributes can be nurtured when environments are conducive to creativity. This scenario of potential and environment is called Trait X State interaction in personality psychology. Actual behavior is controlled by both personal traits and situational states, not just by one or the other. Also, creative individuals from different domains could show variations in their creative traits. Someone who is creative in the arts may be very different from a person creative in math, science, or engineering. In fact, there is no set creative profile that identifies creative individuals in the various domains.

The Creative Process

The *Process* approach to creativity is about how individuals generate original ideas or solutions when they are faced with questions and problems; whereas, the *Person* approach focuses on who is creative. The *Process* approach seeks to capture motivation, perception, learning, thinking, and communicating (Rhodes, 1961, p. 308). Researchers and educators have questioned whether individuals go through similar process to generate creative ideas, or if it is the opposite that the creative process is different for each person. In addition, it remains to be seen how the creative process differs among individuals and if creativity can be taught. Is the creative process specific to the individual? In early 1926, Graham Wallas outlined the four stages of a creative process in his book *The Art of Thought*: preparation, incubation, inspiration, and verification. This four stage model described the creative process as a conceptual anchor. In the *preparation* stage, individuals define problems and gathers information through a composition of observing, listening, asking, reading, collecting, comparing, contrasting, analyzing, and relating all kinds of objects and information (Rhodes, 1961, p.308). The second stage, *incubation* is a period that allows individuals to take time away from the task or problem, so that they may contemplate a wide range of options and solutions for the problem. Individuals can benefit from being relaxed and unrestrained during incubation. The length of incubation depends on each individual: it could last minutes, days, and even longer. *Illumination* is the third stage where the insight actually makes itself know. There is an “ah ha” or “eureka” moment as different ideas and new directions pop into consciousness. Interestingly, the sudden appearance of an idea may imply that insights are quick or sudden, but Howard Gruber’s careful research on discovery indicates that they actually are protracted and take time. Since the person’s thought process is in the incubation stage, he or she is not directly conscious of working on the topic. He or she does not realize that insights are protracted. They may feel sudden, but actually a period of time has passed. The last stage is *verification*. Here the idea is tested and applied. The individual might revisit earlier stages if they think the ideas need more preparation or more time for incubation.

Press Factors

Rhodes referred to *Press* as a term that alludes to the relationship between human beings and their environments. Henry Murray seems to have gone into the most detail about Press factors and distinguished between alpha and beta presses. Alpha press refers to the total objective world. On the other hand, beta press refers to that segment of the objective world that the individual interprets as significant. For example, loud noises lead to reactions and can be distractions to anyone. A certain music can be appealing to someone, but esthetically not appealing to another. Many environmental factors depend on interpretations. Most environmental influences on creative behavior are more beta than alpha press. Many Press aspects have been examined including classroom environment and organizational setting. Resources such as material resources and social resources are quite important. Time is especially important, in part because original ideas may require incubation or at least time for free association and the consideration of alternatives. Time is an example of a social press, because people can be under pressure to complete a project or article before some stated deadline. Some people work well under pressure, they concentrate their effort and can be positively motivated by time limits. Others might prefer to take more time and are distracted by deadlines. The key social press factors include support for new ideas, challenges, trust and permissiveness, and latitude that supports risk taking. Ruth Richard, in her article about the 4Ps that appeared in the first edition of *Encyclopedia of Creativity*, pointed out that it can be difficult to support innovation and creativity in some settings, including

educational settings. In public schools it is challenging to address each students' uniqueness while at the same time addressing the mission of the school system that must satisfy state and federal policy directives. In fact, some environments can limit creativity. Educators must have clear objectives and objective assessments that encourage students to engage their innovative and adaptability capacities, which are the benchmarks of creativity.

Products

Rhodes refers to *Products* as tangible forms manifested from ideas. Ideas are thoughts that are communicated through various mediums. That is, creative products may be novels, poems, scholarly articles, art works, paintings, designs, inventions, or patents, or they may take another form such as performance. Performances are not static forms, but they can still be counted as creative products. Products allow for objective analysis. The problem is that they may not be very predictive. Sometimes, the past is indicative of future efforts, but not always. Additionally, products say little about the actual creative process. In fact, some studies of creative products have focused on examining the product itself rather than the creative process or the talents and effort that went into the product. For example, The Creative Product Matrix contains a list of dimensions that allows for the comparison and ranking of various kinds of products. Many studies of creative products involve eminent persons or experts. This makes sense because they are likely to be creatively productive. Consider, for example, the research on scientific creativity. Products may be publications and citations to them. The latter would be indicative of the quality of a scientist's work because higher quality research is most likely to be cited by others working in the field. Studies of publications as products suggest that there are advantages to interdisciplinary work – some highly creative scientist being polymaths (a person of wide-ranging knowledge or learning), and that a minority of the field produces the lion's share of the research. This last finding is known as Lotka's Law.

Hierarchical Framework for the Study of Creativity

Various lines of research have suggested that the initial creative insight, produced by an individual, is only one aspect of creative achievement. Clearly, there are social factors involved in creativity, and these social factors nurture the personal attributes and personal judgements that are needed to create a new idea or product. Dean Keith Simonton took a social perspective on creativity and defined it specifically in terms of "persuasion." An argument that locates persuasion as a major agent in our larger communicative world. Persuasion fits nicely into our alliterative scheme (as a fifth P), but more importantly persuasion acknowledges the influence of social and historical factors. Put simply, creative achievements change the way that people think and behave. Creative artifacts and performances are influential; they are persuasive.

Simonton's extensive empirical research on social factors also supports Lotka's Law but goes well beyond that. He has tested a large number of cognitive, developmental, and historical hypotheses and derived several compelling *nomothetic theories* about creativity and its impact. Nomothetic theories apply broadly, often across historical eras and, to a certain degree, across cultures. They parallel what are sometimes called universals and can be contrasted with *idiographic theories*, which focus on how individuals differ from one another. Persuasion is also assumed by social theories that focus on attributions as part of the creative process. Attributions of creative value may be given by judges and individuals making up a field of study. The idea here is that an individual may produce something with creative potential, but if judges do not attribute creativity to it, very likely it will have no impact and may very well be ignored and forgotten. If this line of thought holds up, there would be reason to direct one's creative efforts not just to the product, but also to impression management that will increase the likelihood of favorable attributions. This notion has been criticized since it suggests that an individual might benefit from taking time away from creative work so there is time to manipulate attributions. Still, case studies sometimes confirm that eminent creators tend to care a great deal about how their work is received.

Each of the perspectives reviewed in this essay have been organized into a hierarchical framework created by Runco (see **Table 1**). Of most importance is the placement of creative potential and creative performance at the top of the hierarchy. The rationale for this is that many factors, including those describing the creative person and the surrounding press factors, may influence creative effort, but these factors do not always do so. The person and the environment incubate creative potential, but they do not guarantee creative performance. Products, on the other hand, are an end result. A printed text, object, or performance exists in reality. Similarly, new ideas and products are only persuasive if they are complete, or at least manifest. There is a clear separation between perspectives on creativity that describe potential and those that describe actual performance. It is possible that a chronology of sorts can be hypothesized, with particular traits providing creative potential, which are then supported by various press or environmental factors. The results being that a product or performance is created and takes on the social attributes of creativity.

There are advantages to the study of the attributes categorized in **Table 1** as being indicative of creative potential. The table provides a chronology on how to activate potentials and increase creative productivity. The advantage of research on actual performance is that those attributes on the right side of **Table 1** are accessible to objective assessment. Different critical lens can be engaged to analyze a creative object as a social text. There can be consensus about creative things. The

Table 1 Hierarchical framework for the study of creativity

<i>Creative potential</i>	<i>Creative performance</i>
Person Personality Traits, characteristics, idiosyncrasies	Products Patents, inventions, publication, works of art Ideas
Process Cognition	Persuasion Historical impact systems Individual-field-domain Attributions and social judgement
Process Distal influences Evolution Zeitgeist Culture Immediate influences Environments and settings	Interactions State X trait Person X environment

problem with some performance approaches is that, to apply what is learned we must draw inferences from the past to assess the object or performance in the present and the future.

The Five A's Framework

In 2013, Glăveanu proposed the Five A's as a new conceptual framework to reinvestigate creativity: Actor, Action, Artifact, Audience, and Affordance. It extends Rhodes' famous theoretical framework the Four Ps (Person, Process, Product, and Press), which was published in 1961. Rhodes' theoretical work is widely cited and remains one of the fundamental theories of creativity. However, Glăveanu presents a more contemporary model. He acknowledges that Rhodes' approach remains fundamental to his own theory of creativity, which now incorporates a broad conception of social identity.

For decades researchers have attempted to add and elaborate on the definition of creativity based on the Four Ps. It was Glăveanu who was able to rewrite and reorganize the framework to include a broad contextual understanding of creativity. His framework presents an approach to creativity based on socio-cultural perspectives. Table 2 shows how each of the Five As are related to the Four Ps based on creative activity that develops within social and cultural contexts: from person to actor, from process to action, from product to artifact, and from press to audience and affordance. If the Four Ps were focused on elements that constitute creativity, the Five As go further by associating and analyzing the interaction between elements through the lens of sociocultural psychology. In fact, the Five A's suggest viewing and thinking about creativity within broader theoretical perspectives that include social roles and modes of communication.

According to Glăveanu, the concept of *actor* embraces social-cultural psychology whereas *person* covers only the internal attributes of the person. The actor is theorized to exist within social settings that included relationships within a human community. Personal structure should be understood and interpreted within social structure. Therefore, creative *action* is an embedded concept of interrelationship between creative actor and cultural and societal situations rather than creative process itself. That is, the actor cannot be understood separately, and he or she is simultaneously related to audience and societal affordances. Creative action appears out of the relations between actor and audience. These relations create artifacts and the artifacts also can mediate the relations between actor and audience. The dynamic interrelations and integration of each element with social and cultural context are presented in the five A's framework. The artifacts will vary based on how potential actors from the diverse domains interact with different degrees and levels of audience. Interactions between a classroom teacher and students to produce creative artifacts in a school environments differ from the relationships of world-class innovators and scientists who interact with audiences at different levels and distances. The Five A's framework can be applied to various modes and levels of creativity across diverse domains such as art, science, education, entrepreneurship, and so forth.

Table 2 Comparing the four P's and the five A's frameworks (Glăveanu, 2013)

<i>The four P's of creativity</i>		<i>The five A's of creativity</i>
Focus on: Internal attributes of the person Primarily cognitive mechanisms Features of products of consensus around them	Person → Actor Process → Action Product → Artifact	Focus on: Personal attributes in relation to a societal context Coordinated psychological and behavioral manifestation Cultural context of artifact production and evaluation
The social as an external set of variables conditioning creativity	Press → Audience → Affordance	The interdependence between creators and a social and material world

Conclusion

Six Ps (that is, person, process, press, product, persuasion, and potential) and the five A's of creativity are reviewed in this article. There are several intersections and shared points among them. For example, note that at the highest level product and persuasion fuse when considering eminent creators who have wide disbursement and social recognition. Personality research has identified several tendencies (e.g. flexibilities) that have also been uncovered in studies of the creative process. Research on Press and place points to factors in the environment that support the same traits. Importantly, environments that support creative efforts offer certain things and avoid others. Recognizing that there are both supports to creativity as well as barriers, suggests that both be taken into account when assessing creative efforts. Also recall that the impact of environmental factors are frequently moderated by perceptions and interpretations. These factors by definition are constructed by each individual, so it is difficult to make recommendations that apply across all people, settings, and organizations.

The hierarchy in [Table 1](#) is skeletal but nonetheless underscores the fact that some perspectives on creativity assume that only manifest performances are important, while others recognize the more personal side. It is possible to take both personal characteristics and creative performance into account by assuming a developmental process, which suggests that creative potential is a starting point. In summary, if the supports are present (perhaps from creative press and place) potential might be fulfilled resulting in actual creative performance. Creativity may be apparent in actual products and performances that have impacted and persuaded an audience to change its way of thinking. Consider the concept of *framing*. Framing occurs when individuals or activist attempt to change the perception of a problem in order to create new solutions or generate greater awareness. This brief review of the various perspectives of creativity provides a practical guide to recognizing and nurturing creative potential. It is to everyone's advantage if creative potentials are fulfilled and creative products and performances common occurrences. From the Four Ps to the hierarchy of creativity to the Five A's framework, theorizing creativity has broaden over the decades. These frameworks take into account a concept of creativity that stands on particular elements and extends into multidimensional approaches that place the individual in the context of society and culture. The Five A's framework does not specify exact relationships among the elements (actor, action, artifact, audience, and affordance). However, it may be meaningful for new research efforts to discern these multidisciplinary features within a sociocultural psychology analysis.

Introduction

Creativity is an interpersonal, culturally based phenomenon (Glaveanu et al., 2019). Indeed, the creative process and final products created by a single person cannot be separated from their interactions with friends, family, collaborators, and the social context in which they were raised or currently reside. People rely on and collaborate with others to find important problems requiring solutions, gather information, generate and implement ideas, and for subsequent recognition for their ideas. Further, creativity acts as a form of communication and expression that further connects and binds people together. The relationships people form with others represent their own personal social networks. These personal networks are then embedded within the larger social networks of organizations, schools, or societies and the world as a whole.

To develop an understanding of the role of friendships and social networks with creativity, this entry defines what networks are. Next there is a discussion of the role of friendships and social networks for creativity focusing on both the advantages and disadvantages of five commonly studied aspects of personal social networks: network size, network strength, network diversity, brokerage, and network closure.

What Are Social Networks?

Social networks are systems that include “nodes” and connections among those nodes. *Nodes* can be various things such as people, schools, teams, organizations, websites, words, or neurons in someone’s brain. Most social scientists focus on the connections among people across various social systems within schools, organizations, and society more generally. Nodes differ from each other in various ways. If nodes are people, they might differ in characteristics such as sex, age, race, personality, political orientation, values, etc. Formally, the connections among nodes are called edges. *Edges* are also sometimes referred to as ties, connections, or lines. These interpersonal connections can be many different types and be separated into four main types: similarities, social relationships, interactions, and flows (Borgatti et al., 2009). Connections based on similarities might be due to location, different attributes, or membership in various social groups. Social relationships include kin, other roles (e.g., friends or coworker), affective (e.g., liking, disliking), or cognitive (e.g., knowing). Interactions deal with aspects like who talks to who or nodes helping/hurting one another. Finally, flow would be whether tangible or intangible goods (e.g., information, resources) are transferred. Edges can also go one or both ways. *Undirected edges* are those that go both ways. For example, if two people collaborated with one another the edge would be undirected. *Directed edges* are when the connection goes one way. For example, someone might share information with another person, but that other person does not share information back.

A variety of connections have been examined by social network researchers, including collaboration, friendship, knowledge sharing, violence, kinship, romantic relationships, nominations, and more. Although these different networks are often studied separately, there is overlap among them. For example, a friendship network might also overlap with different networks used for communication and collaboration.

Fig. 1 shows an example of a network of tweets from Twitter using a specific Hashtag from a conference on arts, emotions, and creativity. Next, the role of social networks for creativity are discussed with greater emphasis placed on friendship, communication, and collaboration networks as there is likely overlap between these networks and they are more commonly studied. Advantages and disadvantages with friendships as it relates to creativity are considered.

Figure 1 Tweets using the hashtag #artesemocionesycreatividad, which was the hashtag for a conference on arts, emotions, and creativity in Santander, Spain October 9–11, 2019. The tweets were acquired the evening of October 10th. Only 87 nodes and 191 edges are shown, which are those forming a giant weak component (i.e., all nodes within the network are connected to at least one other node in the network, regardless of direction). The two large white nodes represent the Botín Center and the Botín Foundation Twitter accounts. The black nodes represent other nodes using the hashtag. The size of nodes are weighted by network size (i.e., degree centrality). Although edges are directed, they are shown as undirected.

Role of Friendship and Social Networks With Creativity

Friends, provide opportunities for communication and collaboration as well as relief, opportunities to share experiences and information, and more. Simply put, they can provide comfort and a sense of belongingness. Further, friendships help with a person's individual and interpersonal creative endeavors.

An important question is how friendships and other relationships form. Typically, ties between people form through proximity and homophily (i.e., similarity-attraction; Kadushin, 2012; McPherson et al., 2001). Proximity deals primarily with geographical location among people. Two or more people are more likely to form social relationships that live in the same location, work in the same building or for the same company, attend the same school, and/or attend the same events. For children, relationships might also form based on playing together on the playground at school.

The formation and maintenance of friendship and social relationships also depends on homophily/similarity-attraction, following the adage "Birds of a feather, flock together." People that are similar to one another are more likely to create friendships, become close colleagues, form romantic relationships, and many other types of social network ties. The continuation of these relationships also depends on these similarities. The attributes include, but are not limited to the node characteristics mentioned above.

For creativity as a binding force, people seem to connect with people who are similar to them. There is a relationship between receiving similar scores on a creativity task and nominating other people as one's friend (McKay et al., 2017). People sharing a preference for engaging in creative activities appear to form and maintain relationship based on these similarities. Further, they might be more likely to attend similar events and enjoy similar activities and hobbies. Although these reasons likely drive this relationship, further research is necessary to determine why the formation of friendship has to do with creativity.

Social network and creativity researchers often study people's personal networks. That is, while many people make up a larger social network (called "whole networks"), often times the focus is on a single person's individual network (called "ego networks"). When focusing on the relationship between ego networks and creativity, it is more nuanced and complex than simply saying that social relationships are beneficial for a person's creativity because what represents a person's social relationships is complex. This entry focuses on five aspects of social networks and their relation to creativity: network size, network strength, network diversity, brokerage, and network closure. Each of these aspects and their advantages and disadvantages for creativity will be explored.

Network Size

One way to conceptualize how friendship relates to creativity is to consider the number of friends within a person's network. This is called *network size*, which is formally called "degree centrality" by social network researchers. Generally, the relationship between network size and creativity is positive (Baer et al., 2015; Kéri, 2011; McKay et al., 2017). That is, as the number of friends within someone's personal network increases so too does their creative performance. This positive relationship is due to a few related reasons. First, people have more opportunities and people to share and discuss information with. Because creativity involves obtaining information to generate new and useful ideas, people need to know what has been done before, what other similar people are working on, and what information they might need to know for their work. That way, they can create something novel and useful. Second, people have more collaborators they can work with. Creative work often involves lots of hard work and trial-and-error. Friends and colleagues help someone deal with the laborious effort creative work requires, speeding up the process to find a viable idea. Larger networks typically help people navigate the complexity that is creative work.

Although the relationship between the number of friends in someone's personal network and creative performance is positive, there are disadvantages to having a large personal network. With large networks, the time a person can devote to creative efforts can also decline. Although the help someone receives from others benefits their creativity, people must divert their attention to maintaining these friendships and colleagues. Although the time spent getting to know your friends and colleagues better – and your friend/colleague getting to know you better in return – is meaningful, it takes time and attention away from creative tasks or projects. This can result in creative work taking more time, rather than less. Additionally, people might receive lots of conflicting information, ideas, and suggestions from others. In such cases, deciding the best course of action with creative work is more difficult. In sum, there is a positive or inverted U-shaped relationship between network size and creativity. A large network can be beneficial to someone's creative work, but at a certain point too many friends and colleagues can become detrimental. There is no magic number that can be offered as it depends on a creator's personality and environmental factors (Baer, 2010).

Network Strength

In addition to network size, the strength of relationships within a person's network is important. *Network strength* focuses on the quality of relationships with someone's personal network. The strength of relationship within a person's network is based on three factors (Granovetter, 1973). First, closeness reflects the emotional closeness of relational ties. Second, duration reflects how long the relational tie has persisted. Last, frequency is how often people interact. Typically, ties are considered either "weak" or "strong." Weak ties are those people are not emotionally close with, have known for a short duration, and talk to infrequently. Strong ties are those people are emotionally close with, have known for a long duration, and talk to frequently. For younger children, strong ties might reflect who they play with on the playground regularly. For teenagers, it might be who they spend their free time with or eat lunch with. For adults, this might be who they spend their free time with and close colleagues in their organization that they share and discuss information and ideas with frequently.

Tie strength is often examined in two ways. First, the *number of strong ties* and *number of weak ties* is examined. This approach mixes network size and strength together, which can create issues in determining whether creativity is due to network size or strength. Second, *network strength* is treated as a separate factor from network size, thus parsing the two effects out from one another. Overall, the relationship between network strength with creativity and innovation is positive (Baer et al., 2015). That is, when the strength of a person's network contacts increases their creative performance also increases too. Similarly, number of strong ties is also positively related to creative performance, whereas the number of weak ties is unrelated to creative performance.

The benefits from strong ties are due to a relationship built on trust and the frequency in which people communicate. Strong ties are more easily available and reliable (Coleman, 1990). You can more easily get in touch with them when you need their assistance. Strong ties are also those someone can more openly discuss ideas with in general without fear of them being stolen and also more radical and outlandish ideas that might be seen as high risk by others. Strong ties also play an important role when trying to implement ideas as close ties can provide "buy-in" to getting one's ideas implemented (Baer, 2012).

Although strong ties are beneficial for creativity, there are also drawbacks for these ties and instances where weak ties are beneficial. When people know each other over long durations and communicate frequently, the unique experiences and information between each person decreases. Strong ties then would only be able to provide redundant information over time. Given the importance of diverse ideas and perspectives for creativity, this redundant information would provide limited benefit for someone's creativity. In such cases, weak ties would be beneficial given they provide novel or nonredundant information. This novel information would especially be useful during early creative process stages like idea generation (Perry-Smith and Mannucci, 2017). Specifically, when generating ideas, weak network ties might be more useful for obtaining information and ideas. However, whether people are able to utilize this information for creativity depends on a person's personality. Specifically, research has shown that the personality trait openness to experience allows people to more effectively use the information provided (Baer, 2010).

Network Diversity

One underlying assumption for weak ties is they provide novel information. Although this might sometimes be the case, it is not always true. That is, weak ties could have the same functional and demographic backgrounds, which would mean the network

contact is homogenous to a given creator. Thus, it is important to consider and examine network diversity separate from network strength. Network diversity reflects differences among a person's network contacts with regard to functional, task-oriented differences (e.g., tenure, educational background) or demographic, relational-oriented differences (e.g., age, gender, race; Baer et al., 2015). A person's network diversity plays an important role as such diversity likely reflects unique experiences and information that can be of high importance for creativity and innovation. Indeed, prior research has demonstrated that network diversity is positively related to creative and innovative performance (Baer et al., 2015). This positive relationship, however, appears to be driven by functional differences within a person's network. That is, being able to obtain different ideas and perspectives is important. Demographic, or relational-oriented differences, is unrelated to creativity and innovation. Thus, the positive relationship between network diversity and creativity depends on the type of diversity within a person's network.

Brokerage

In addition to network size, strength, and diversity, a person's location within the whole network also plays an important role. Typically, the focus of one's location deals with whether a person bridges structural holes or serves in a *brokerage* position (Burt, 2004). Structural holes are gaps within the larger whole network. Thus, a person who fills these gaps and connects otherwise disconnected groups within a network has a potential advantage when it comes to creativity. These people are often referred to as "brokers" as they control the flow of information and other resources among two or more groups. Thus, these people have first access to nonredundant information, which provides them an advantage for using this information for their own work. Further, this first access provides someone autonomy to decide what they want to share and when they want to share it. Overall, brokerage is positively related to creativity and innovation (Baer et al., 2015).

Although there are many benefits to brokerage and filling structural holes, there are also potential disadvantages. First, if everyone within a network were trying to act like a broker, the benefits would disappear as the structural holes are now filled by multiple people. If everyone were filling a structure hole, that hole would no longer exist and no one would have first access to information or ideas. However, it is rare for all individuals to pursue brokerage positions as people's needs differ, influencing the types of personal networks they construct (Kadushin, 2012). Further, if a broker continuously obtained new information and did not share it, people would trust them less. This withholding of information, even by accident, would lead to both groups they span across unwilling to share more information. In the long run, this would harm the advantage of the broker's creative performance. Although brokerage is beneficial for creativity, it is important for brokers to understand the potential disadvantages of filling structural holes.

Network Closure

In addition to the above aspects, the extent other people within a person's network are connected together, or *network closure*, also impacts a person's creativity. Closed, or "dense," networks reflect instances when a person's network contacts are also strongly connected to each other. Given such strong ties are built on trust, it creates a larger social system with social norms where people would be less likely to exploit others (Coleman, 1990). Indeed, if someone were to exploit another person within the group, they would have to fix the wrongdoing, be punished, and/or be forced to leave the group. Because of these social norms, people would be more likely share critical information openly and coordinate seamlessly with each other, which might facilitate creative work.

Although there might be potential benefits of closed networks for creativity, the overall relationship between closure with creativity and innovation is negative (Baer et al., 2015). A dense personal network can restrict the flow of novel information, leading to ideas being low in creativity. Further, dense personal networks might result in people being more risk averse as they do not want to violate the social norms. This avoidance of risk taking will push people to conform more to those around them. This might seem contradictory to the benefits of network strength discussed above. However, network strength focuses on the ties to the focal person, whereas network closure deals with the relationships among the other ties within that focal person's network. Hypothetically, a person could have ten strong ties that are weak ties with one another (i.e., strong ties with a sparse closure), whereas another person might have ten strong ties that are also strongly connected to one another (i.e., strong ties with dense closure). These differences are important to consider for how network strength and closure relate to creativity and innovation.

Conclusion

Friendships and social networks not only play an important role in someone's life overall, but also for their creative and innovative work. This entry focused on five aspects of personal networks often studied in the social networks and creativity literature: network size, network strength, network diversity, brokerage, and network closure. Bigger personal networks typically help for creativity, but it is important to be mindful of networks that are too large as there are diminishing returns. Strong network ties typically help with creativity, but weak ties also play an important role as well. More diverse networks are important for obtaining differing perspectives and novel information, but this diversity should focus on functional rather than demographic differences. Brokers typically benefit from filling structural holes in larger social networks, but these benefits must be handled carefully. Finally, closed networks are

typically not as beneficial for creativity, but a strong collaborative group might hold benefits in other ways. This double-edge nature of social networks for creativity is important to consider when people use and gain assistance from their social networks.

Introduction

Research investigating the neuroscience of creativity has taken off in the last decade. Using neural techniques as a tool, scientists have investigated brain correlates of artistic planning and creative thought, traits of highly creative people, and reactions to artistic works. Using techniques like electroencephalography (EEG), positron emission tomography (PET), diffusor tension imaging (DTI), and transcranial direct current stimulation (tDCS), scientists have steadily begun to understand the neural activity supporting the creative process. The majority of research, however, has relied on magnetic resonance imaging (MRI) and functional magnetic resonance imaging (fMRI). fMRI utilizes blood oxygen level-dependent (BOLD) imaging because local consumption of oxyhemoglobin and conversion into deoxyhemoglobin represents a reliable, ferromagnetic marker for changes in neural activity. Measuring regional variations in BOLD signals thereby serves as a corollary of neural activity that allows researchers to map changes in brain activity associated with a wide range of cognitive, motor, or sensory tasks germane to creative processing in the brain. The strength of fMRI as a technique lies in the fact that it is non-ionizing and non-invasive, yet provides high spatial resolution.

Neuroscientists have largely taken two approaches to studying artistic creativity. One burgeoning approach studies the neural responses to works of art, sometimes referred to as the study of neuroaesthetics. The other approach examines neural responses involved in actively planning or creating art. This chapter focuses on the latter approach, surveying fMRI experiments that investigate the neural correlates of musical, visual, and verbal creativity, as well as nascent knowledge regarding kinesthetic creativity and the creativity of design and invention. While many expressive art forms exist, these fields discussed here represent performing art forms that have been the most widely investigated, to date, using neuroimaging techniques such as fMRI.

Musical Creativity: Improvisation

The majority of neuroimaging experiments on creativity thus far have focused on musical creativity rather than other art forms. This is likely due to the motor constraints placed on participants when lying in a fMRI scanner. Excessive movements by the participant cause artifact and blurry images, thus making it hard to study dance gestures, for example. With music, however, many researchers have found ways to circumvent these scanner-induced motor constraints. Participants lie supine in the scanner, and mentally improvise (Lu et al., 2017) or play custom-made nonferromagnetic keyboards (Bengtsson et al., 2007; Limb and Braun, 2008; de Manzano and Ullén, 2012a, 2012b; Pinho et al., 2014) or button boxes (Berkowitz and Ansari, 2008, 2010) held on their knees (Fig. 1).

By having participants play with their hands while holding other parts of their body immobile, investigators are able to acquire clear neural images while studying musical creativity. In addition to scanner-related adaptations, the mathematical structure of music makes it well suited for scientific manipulation, allowing for the design of well-controlled experiments intended to elucidate specific aspects of musical processing in the brain.

Adult Musicians and Improvisation

Music as an art form consists of many creative behaviors such as composing or expressive interpretation of musical phrases. Most experiments on musical creativity, however, have focused on improvisation, as it represents a “window into real-time creative processes” (pg. 1, [Loui, 2018](#)). Musical improvisation is a sophisticated process involving the rapid generation and production of novel melodic, harmonic, and rhythmic musical elements. An improvising musician must generate ideas and realize them on the instrument immediately, all while attempting to create aesthetically meaningful music within a particular musical context.

Early experiments had participants perform memorized or pre-learned tunes during the control task and improvise upon those tunes for the experimental task. For example, professional Classical pianists improvised based on a visually displayed melody in one condition, and then reproduced the previous improvisation from memory for the control condition. Improvisation resulted in activations in the right dorsolateral prefrontal cortex (DLPFC) and pre-supplementary motor area (preSMA), dorsal premotor cortex (PMd), and the left posterior superior temporal gyrus (STG) ([Bengtsson et al., 2007](#)). In an experiment studying professional jazz musicians, participants performed a pre-memorized jazz composition over a jazz track for the control task, and then improvised on that same tune for the experimental task ([Limb and Braun, 2008](#)). Improvisation resulted in a distinctive pattern of neural activation and deactivation—specifically a deactivation of the DLPFC and limbic areas, coupled with a simultaneous activation of the medial prefrontal cortex (MPFC), portions of the superior and middle temporal gyri (STG and MTG) involved in sensorimotor activity, and the anterior cingulate cortex (ACC). Neural activity in these two experiments thus showed different patterns of activity, likely due to differences in participants (classical vs. jazz musicians) as well as task demands (more free improvisation in [Limb and Braun, 2008](#)). Freestyle rap has also been investigated as an art form that lies at the intersection of music and spoken language ([Limb, 2010](#); [Liu et al., 2012](#)). Functional MRI of rappers revealed increased activity in left hemisphere language areas which is unsurprising given the genre, as well as a pattern of increased activity in the MPFC and preSMA and decreased activity in the DLPFC during freestyle rap improvisation ([Liu et al., 2012](#)).

Melodic vs. Rhythmic Improvisation

Other experiments have compared melodic versus rhythmic improvisation in order to identify differences in neural activity when the improvisation process is more constrained. Classically-trained college pianists improvised with pitch or rhythms while performing novel five-note tunes (experimental task) or pre-learned tunes (i.e., repeated pitches or ascending/descending scale for the control task). Both rhythmic and melodic improvisation activated the rostral cingulate zone (RCZ) of the ACC, the inferior frontal gyrus (IFG) and ventral premotor cortex, and the PMd, suggesting this network is generally involved in the invention of novel motor sequences. More specifically, melodic improvisation activated the right premotor cortex and left cerebellum and deactivated the right superior and medial frontal gyri, right angular gyrus (AG), and posterior cingulate ([Berkowitz and Ansari, 2008](#)). In another experiment comparing melodic versus rhythmic improvisation, researchers found that melodic improvisation activated more of the PMd, while rhythmic improvisation activated the preSMA, although there was some overlap of involved regions for both conditions ([de Manzano and Ullén, 2012a](#)). Moreover, the rhythmic improvisation condition resulted in more functional connectivity between

Figure 1 The experimental setup used in [Limb and Braun \(2008\)](#) as well as other fMRI experiments of musical creativity. A non-ferromagnetic keyboard (or button box) lies on the participant's lap while the head lies stationary in the magnetic bore of the fMRI machine. Participants see their hands and the keyboard via the mirror attached to the facemask used in the fMRI machine. When playing the piano, only the fingers move thereby allowing the participant to keep the head still enough to acquire high-quality images in the scanner.

the preSMA and cerebellum. Thus, it appears that the type of improvisation—focusing on pitch vs. rhythm—influences the brain networks involved. Although there was a degree of overlap in brain areas involved in these two types of improvisations (Beaty, 2015) and testing paradigms were slightly different, it appears that the pre-supplementary motor area was more active during rhythmic improvisation while the premotor cortex was active during melodic improvisation (see additional discussion in McPherson and Limb, 2018).

Collaborative Improvisation

While solo improvisation is quite common, jazz performances often involve collaborative improvisation between performers. In the single fMRI experiment on collaborative improvisation, jazz artists performed a common improvisational technique known as ‘trading fours,’ where jazz musicians exchange improvised materials in 4-measure units. The participant lay supine in the fMRI scanner while the experimenter responded musically to the participant from outside the scanner, taking turns improvising in a musical ‘conversation.’ For the control condition, the two individuals simply alternated pre-memorized 4 bar segments of a melody using their right hand rather than musically responding to each other. Given the language-like quality to these improvised musical exchanges, the experimental condition lead to activation of left hemisphere cortical areas and right hemisphere analogues generally associated with language (i.e., perisylvian language areas, Donnay et al., 2014). In contrast to a deactivation of the DLPFC seen in Limb and Braun (2008); this paradigm showed an activation of the DLPFC, perhaps due to the additional social component involved in collaborative playing and the increased need for working memory in order to respond effectively to musical partners.

Expertise and Improvisation

Not surprisingly, neural activation when improvising varies according to one’s expertise or training level in improvisation. For example, in one experiment comparing musicians to nonmusicians, musicians showed a deactivation of the right temporoparietal junction (rTPJ), thought to reflect an expertise-related focusing of goal-directed attention and filtering of irrelevant stimuli (Berkowitz and Ansari, 2010). Different genres of music also rely more heavily on improvisation than others. Jazz, for example, involves more improvisation than Classical music which may be why jazz musicians have enhanced perceptual sensitivity to unexpected musical events compared to Classical musicians (Przyssinda et al., 2017). Additionally, expert improvisers often perform differently from beginner improvisers. In an experiment testing jazz and classical musicians who had spent varying amounts of time practicing improvisation across the lifetime, more highly trained improvisers had lower activity in frontal parietal association areas and greater functional connectivity between prefrontal, premotor, and motor regions of the frontal lobe (Pinho et al., 2014). Because these effects were specific to improvisation experience and independent of piano experience or age, this suggests that improvisation taps into an independent neural network from the network built by practicing an instrument. The ability to improvise utilizes a different network than the one that undergirds the ability to play the piano. This makes sense considering that creativity in improvisation is not simply a matter of freely selecting individual notes or sounds; expert improvisers rely on long-term knowledge of musical patterns and musical structures that can then be called upon rapidly, using simpler structures to build more complex performances (Pressing, 2001). Higher functional connectivity in expert improvisers may reflect that their brains are reorganized to automate these processes, making them more efficient at tapping into pre-learned motor patterns and strategies (Beaty, 2015; Pinho et al., 2016).

The Impact of Context on Improvisation: Emotion

While long-term training can thus lead to differences in neural activation or functional activity while improvising, short-term effects exist as well. Context shapes the neural networks involved in improvisation. For example, several studies have investigated the impact of emotion on improvisation. In one fMRI experiment, professional jazz pianists were shown photographs of an actress depicting a positive, negative or ambiguous emotion. The participants then performed improvisations that they felt expressed the emotions in the cue cards. It was found that the emotional intent modulated brain activity. For example, ambiguous and negative improvisations demonstrated heightened activity in the right insula, ACC, right parietal cortex, bilateral middle temporal lobes, and bilateral prefrontal cortex compared to positive improvisations. Positive emotion improvisations showed more cerebellar activity as well as more pronounced deactivation of the DLPFC compared to negative improvisations. Musical creativity is thus context-dependent; emotional state can influence the neural mechanisms underlying improvisation (Mcpherson et al., 2016).

Other experiments have likewise shown that neural networks involved for improvisation are highly task-dependent. In an experiment where trained musicians had to either improvise with a given pitch set (tonal or atonal pitch sets) vs. free improvise with a certain emotional content (happy/fearful), it was found that the pitch set conditions saw an increase in activity in the DLPFC as well as higher functional connectivity between the premotor and parietal areas. By contrast, for the emotional conditions, there was a deactivation of the DLPFC and greater functional connectivity with the default mode network. The authors believed that these two networks formed two different pathways by which creativity could be completed; the pitch set condition required memory and a more explicit approach and thus the DLPFC was more active to synthesize sensory and goal-related information. By contrast, the emotional condition might have used more of an implicit strategy that favored spontaneity and flexibility, thereby relying on the default mode network which automates processes (Pinho et al., 2016). These experiments illustrate that constraints upon the improvisation shape the neural network supporting the creative process.

Summary: Neural Networks Involved with Musical Improvisation

Researchers have used different paradigms, equipment, and participant groups to investigate musical improvisation which may explain the disparities in results seen across studies (Dietrich and Kanso, 2010; Bashwiner, 2018; McPherson and Limb, 2018). Nevertheless, neuroimaging experiments generally show that the frontal temporal, parietal, premotor and secondary auditory areas are regions of interest. Specifically, structures like the MPFC and cingulate cortex, the DLPFC, inferior frontal cortices (e.g., inferior frontal gyrus), dorsal premotor areas (for motor planning and sequencing), and presupplementary and supplementary motor areas are associated with improvisation (Pinho et al., 2016; Bashwiner, 2018; McPherson and Limb, 2018).¹ Frontal activity is particularly interesting as improvisation often leads to increased activity in the MPFC with decreases in DPFLC activity (Loui, 2018). Moreover, researchers have noted that prefrontal activity varies from study to study depending upon the expertise level of participants, the cognitive demand of the improvisation task, as well as whether the improvisation is loosely or tightly constrained.

These brain structures active during improvisation belong to several functional networks such as the default mode and executive networks (Beaty, 2015; Loui, 2018). The executive network (which includes mesial prefrontal regions like the MPFC and cingulate cortex) is often active during tasks that require cognitive control, while the default mode network (which includes cortical midline and posterior parietal areas like the DLPFC, inferior parietal regions, parahippocampal gyrus, hippocampus) is associated with defocused mind-wandering, internally-directed thought, and a state of 'flow.' While these two networks may seem like opposing forces, the fact that they are concurrently active during improvisation suggests that rather than being opposites they simply show "differential involvement as a function of task demands" (pg. 115, Beaty, 2015). Recent brain connectivity research has shown that the salience network (comprised of the bilateral insula and ACC) may serve as a conduit between the default and executive networks, identifying ideas generated during improvisation by the default network and forwarding this information to executive systems for higher order processing such as evaluation or revision (see discussion in Beaty et al., 2018). Indeed, highly creative people (as measured by their divergent thinking abilities) show dense functional connections between the default, executive, and salience brain networks (Beaty et al., 2018). The complexity of regions involved in improvisation mirrors the complexity of improvisation itself. An improviser generates new ideas, but also selects and evaluates them quickly, utilizing both the default network and the executive network (Loui, 2013). From an artistic standpoint, musicians simultaneously control the creative process by selecting musical ideas and implementing them, while at the same time "letting go" in order to allow the music to unfold holistically and organically. Thus, improvisation requires a degree of automation, and yet is also generative. Neural imaging experiments illustrate this duality, with musical improvisation tapping into large-scale brain networks that support cognitive control and focused attention concurrently with spontaneity and creativity.

Visual Creativity

Exploration is underway to examine whether neural networks underlying creativity are domain general or idiomatic to a particular artistic genre (de Manzano and Ullén, 2012b; Beaty, 2015). As mentioned previously, the majority of experiments on creativity have focused on musical creativity, however, a small subset of studies have explored neural activity associated with the visual arts. In a case study of an artist sketching a portrait, decreased activity in the fusiform gyrus was found when the artist was copying drawings of faces (Solso, 2001).

Group experiments have investigated the neural correlates underlying visual creativity tasks and artistic planning. Some researchers have found an association between the right parietal lobe and visuospatial processing (Gansler et al., 2011). Other researchers have found that visually creative tasks lead to increased activity in left middle and inferior frontal lobes and decreases in activity in the right middle frontal lobe and left inferior parietal lobe (Huang et al., 2013). In one study of visuospatial creativity, architects and architecture students either mentally rotated shapes into a larger recognizable shape (the control task, a convergent thinking task) or performed a right-hemisphere task where they arranged three distinct shapes into a creative composite image (the experimental task, a divergent thinking task). Both tasks activated the parietal cortex bilaterally and motor regions known to be involved in visuospatial rotation of objects. However, the creative task in this particular experiment led to higher activation in left hemisphere regions like the posterior parietal cortex, premotor cortex, DLPFC, and MPFC (Aziz-Zadeh et al., 2013), similar structures that have been linked to musical improvisation.

In another experiment, participants played Pictionary™ using an MR-safe tablet. For the experimental task, they drew certain words (ex., 'snore', 'graduate') while for the control task they made a drawing for the control word ('zigzag'). This paradigm therefore allowed an investigation of figural creativity without explicitly instructing participants to be 'creative.' The drawing condition led to increased engagement of the cerebellum, thalamus, left parietal cortex, right superior frontal, left prefrontal and paracingulate regions (Saggar et al., 2015). Thus, compared to musical improvisation, some overlap exists for the neural correlates underlying this visual creativity. In particular, decreased activity in the ACC/DLPFC was associated with more highly creative drawings, similar to the neural activity in the jazz experts tested in Limb and Braun (2008). Additionally, visual creativity led to increased activity in the cerebellum, mirroring the results from Pinho et al. (2014) studying musical improvisation.

¹In one experiment comparing improvisation to pseudorandom response generation, it was found that similar brain structures were involved for these two generative tasks; real-life creative behaviors like musical improvisation are controlled by the same cortical network that allows other forms of free generative action. Further research is necessary to explore what separates "creative from non-creative cognition" (pg. 779, de Manzano and Ullén, 2012b).

This brief survey shows that disparities are seen across studies due to the differences in task demands, paradigms, and participants (for a more detailed review, see the meta-analysis in [Pidgeon et al., 2016](#)). More research is necessary but it has been posited that different neural systems are used at different points in the artistic process. [Heilman and Acosta \(2013\)](#) theorize that during the innovative stage when a creative artist is planning a picture, the artist may recruit global attentional systems of the right hemisphere. However, later during the production stage which necessitates a focus on details, the artist may rely more heavily on the left hemisphere's focal attentional systems, and/or intermittently switch between these systems ([Heilman and Acosta, 2013](#)). One functional connectivity experiment has begun to delve into the neural substrates underlying visual composition planning. In an experiment investigating visual artwork planning, professional artists and a matched group of control participants completed three tasks while scanned in a fMRI machine ([De Pisapia et al., 2016](#)). Participants performed: 1) a control block involving mind wandering and defocused thinking, 2) a control block where they had to visualize the letters of the alphabet from A to Z and imagine drawing them thereby performing a repeated visual imagery task, and 3) an experimental block where participants were given 8 minutes to create and visualize a landscape (either geographical or metaphorical). Afterwards, artists immediately sketched out their planned artwork (see [Fig. 2](#)). Functional connectivity analysis revealed that the creativity task resulted in higher connectivity between the executive network (EN) and the default mode network (DMN), with professional artists showing this difference more strongly (particularly the connection between the precuneus of the DMN and the cingulate cortex, premotor cortex, parahippocampal cortex/fusiform gyrus, DLPFC and associative visual cortex). Obviously further research is necessary, but planning a visual art composition appears to activate similar neural networks to those involved in musical improvisation. As mentioned previously, creativity is a balance between idea generation and evaluation, convergent thinking and divergent thinking, and therefore brain activity shows an interplay between the executive network and the default mode network. Comparing these visual art experiments to research in the field of music illustrates that creativity has certain neural correlates that are domain specific (ex., the visuospatial regions activated for visual creativity tasks vs. the secondary auditory areas activated in music improvisation experiments) while other brain networks may underlie creativity across artistic domains, supporting creativity in a domain general manner.

Verbal Creativity

One form of ubiquitous 'everyday creativity' is the fact that humans converse with one another without a pre-written script. Recent fMRI neuroimaging experiments have begun to look at more formal forms of verbal creativity such as written humor ([Amir and Biederman, 2016](#)), creative story generation ([Howard-Jones et al., 2005](#); [Shah et al., 2013](#)), and poetry composition ([Liu et al., 2015](#)). When generating either a mundane (control task) or humorous (experimental task) caption to a presented *New Yorker* cartoon, expertise effects were found in a participant group of professional and amateur 'improv' comedians. Greater comedic experience was associated with decreased activation in the striatum and MPFC, but heightened activation in temporal association regions ([Amir and Biederman, 2016](#)). In contrast, amateur improv artists showed increased activation of the MPFC ([Amir and Biederman, 2016](#)). Expert comedians, in short, may be relying more on the spontaneous flow in their creative process as has been seen in musical experts as well ([Limb and Braun, 2008](#)).

Researchers have begun to look at neural activity during subprocesses of the creative writing process, from brainstorming (planning a story) to creative writing (actually writing a continuation of a given literary text out by hand, see [Fig. 3](#)) ([Shah et al., 2013](#)).

Figure 2 Example of artwork generated during visual planning experiment, figure adapted from [De Pisapia et al. \(2016\)](#). Left panel (A) is a sample initial sketch done by a participant directly following the fMRI scanning session while right panel (B) is the final artwork, completed in the weeks following the experiment. A selection of the artistic compositions generated from this experiment were displayed in a museum exhibition entitled "In resonance: snapshots of creativity in the brain" (*In risonanza: istantanee di creatività nel cervello*, 2013–2014) at the Museum of Contemporary and Modern Art of Rovereto and Trento (MART) in Italy.

Brainstorming activated language processing areas such as the bilateral inferior frontal gyrus (IFG) and left temporal areas, hierarchical organization in the prefrontal cortex, and cognitive decision processes in the dorsal ACC. Compared to simply copying text (the control condition), creative story generation lead to activation in areas associated with memory retrieval, semantic integration, free association and spontaneous cognition, located in a left fronto-temporal network including the left IFG and left temporal pole. In an experiment where participants created stories from a given set of words, creativity story generation was similarly associated with an increase in prefrontal areas like the bilateral medial frontal gyri and left ACC (Howard-Jones et al., 2005).

While many of the experiments on creativity have focused on the generative phase where ideas are produced rapidly, relatively little attention has been paid to the revision process, where ideas are modified and adapted. In an experiment on poetry composition, generating a new poem lead to a dissociated pattern of increased activity in the MPFC and decreased activity in the DLPFC, similar to what has been found in spontaneous music improvisation (Limb and Braun, 2008). During the revision task where participants edited the aesthetic content of their poems, however, the neural activity was the opposite of the generation phase, showing activation of the DLPFC and intraparietal sulcus. Thus, this experiment illustrates that different parts of the creative process lead to reciprocal changes in prefrontal and parietal areas. While there are still relatively few experiments studying the creative writing process, the existing neuroimaging experiments excel at subdividing the creative process into components to look at neural activity with each associated stage.

Kinesthetic Creativity and Design Creativity

This chapter has primarily focused on fMRI experiments of musical, visual, and verbal creativity. Researchers, however, have begun to branch into investigations of kinesthetic creativity. Given the motion constraints of the fMRI scanner, physical gestures are naturally quite difficult to study. For this reason, rather than investigating neural networks associated with the actual performance or execution of physical gestures, experiments have instead focused on the neural activity underlying motor planning rather than motor production. For example, in a study of trained ballroom dancers, scientists used a novel paradigm where the dance participants used bimanual contact with an experimenter standing by the fMRI magnet bore and the two of them would alternate acting as the leader or follower in joint “improvised” dance movements. As with musical improvisation, dance improvisation (in comparison to fixed movement patterns) revealed the importance of premotor and working memory areas such as the PMd, SMA, IFG, DLPFC, STG, and putamen (Chauvigné et al., 2018).² In an experiment where participants watched videos of a soccer scene and then had to imagine a creative or obvious move as a continuing play, soccer-specific creativity tasks modulated activation levels in visual and sensorimotor areas (Fink et al., 2018). Thus, neuroimaging investigations of dance, sports, or other motor creativity remain relatively scarce but are beginning to investigate motor planning and creative motor imagery.

Another burgeoning field is the neuroscience of design creativity which allows the creation and development of artifacts, processes, symbolic systems, scripts, laws, behavior and so forth to solve complex problems in the modern world (for a detailed review, see Lazar, 2018). While a more comprehensive summary lies beyond the scope of this chapter, recent fMRI experiments have looked at the neural activity associated with designing book covers (Ellamil et al., 2012), arranging furniture within a constrained space (Gilbert et al., 2010), or designing a new tool such as a pen (Kowatari et al., 2009). Currently, existing experiments

Figure 3 Experimental setup used to investigate neural correlates of a creative writing task, figure adapted from Shah et al. (2013). Participants used an MR-safe writing desk while lying prone in the fMRI scanner. An experimenter stood next to the scanner to switch out the sheets of paper as the participants completed the task of writing out the continuation of a story by hand. Participants could see their hands and written text using the double-mirror attached to the head coil.

²For a review of the neural correlates underlying dance perception, dance expertise, and dance gestures, see reviews in Karpati et al. (2017) (Cross and Ticini, 2012; Karpati et al., 2015).

show that design cognition utilizes brain networks that only partially overlap with regions associated with musical, verbal, and visuospatial creativity although these studies use a wide variety of tasks and future experiments are needed (Lazar, 2018).

Conclusions and Future Directions

This chapter has briefly surveyed neuroimaging experiments investigating artistic production and planning. These experiments have revealed neural correlates that are idiomatic to particular artistic domains as well as substrates that are domain general. The creativity underlying artistic production generally consists of idea generation, evaluation, and automation of overlearned processes or motor movements, therefore striking a balance between involvement of both the default mode network and the executive network. Naturally, movement constraints exist with using a fMRI scanner and lying motionless and supine in the machine is not the most ecologically-valid or ideal setting for artistic inspiration. Nevertheless, research in the last decade has made strides towards understanding the neural activity associated with artistic production, even if fMRI experiments utilize a wide variety of paradigms, tasks, and populations. Even for musical creativity, the most-studied artistic field, many unanswered future questions remain. As discussed in this chapter, creativity is a multifactorial process (Dietrich, 2004). Future experiments will have to further explore the sub-processes underlying creative production (such as with experiments examining the generative phase vs. the revision phase) and continue to look at creativity across different art forms.

Moreover, while experiments examining the effects of expertise exist, more research is necessary to compare non-experts to amateur artists to expert artists. On a related note, relatively little is known about whether creativity changes across the lifetime. Are there age-related differences in creativity? Finally, are variations in artistic creativity due to innate differences or extensive training? What are the exact brain changes that occur due to creativity-induced neural plasticity? Using longitudinal studies of creative vs. non-creative interventions, science may begin to gain a deeper understanding of how creativity shapes the brain. With that knowledge, we may then be able to translate research into real-world interventions to increase creativity in the general population. In a time when the arts and the importance of creativity can be politically and educationally undervalued, scientific interdisciplinary work as described here is more necessary than ever. Despite the vital role played by creativity in human achievement throughout history, our understanding of how creativity unfolds in the brain remains incomplete. While it is difficult to study creativity and improvisation (by nature novel and spontaneous) using the scientific method (by nature systematic and rigorously-controlled), it is an enterprise of critical importance. Efforts to increase and maintain creative abilities over the lifetime and in a variety of fields is crucial, as creativity is considered an 'intangible asset' for future success (as discussed in Fauth et al., 2009), whether in everyday activities or in developing society's cherished works of art.

Glossary

Bronies Participants in fan communities who share their enjoyment of the *My Little Pony* franchise. They are often identified in mainstream discourse for the non-normative demographic characteristics of being teenaged and young adult males.

Cosplay Products and performances created by members of fandom communities that emerge from the tailoring of fantastic costumes as works of art.

Fanart A variety of art practices, inclusive of drawing, painting, tailoring, sculpture, and stop-motion animation, among others, that expresses identification with a fandom community.

Fandom A subcultural community that exists to express a shared enthusiasm for a topic. These topics can vary in extremes, in some cases being extremely abstruse, rarified, and sophisticated, and in others being broad, open, and easily apprehensible.

Fanfic A variety of literacy practices, inclusive of producing short stories, poetry, lyrics, and fantasy worlds, among others, that expresses identification with a fandom community.

Furries Participants in subcultural communities who develop and enact identities based on anthropomorphic animal characters.

Incel Participants in androcentric subcultural communities who emphasize their 'involuntary celibate' status. They are often identified in mainstream discourse for the potentially harmful and misogynistic character of their ideologies.

Therians Participants in subcultural communities who feel, for personal or religious reasons, that they share in the spiritual essence of an earthly, non-human animal.

Introduction

Who are geeks? This question might immediately invoke a response in reflex: The image of a person with glasses, nasality, educational ambition, perhaps poor personal hygiene and very poor social skills. The reason for this is not complicated. In their most stereotyped form, geeks are very familiar to individuals from a variety of cultures, though displaying mild local variation in connotation and nomenclature. They are, for example, referred to as "nerds" or "dweebs" in different communities around the United States. Similarly, they are sometimes referred to as "boffins" or "keenos" in England, "otaku" in Japan, and "strebers" in Germany.

Given the wide availability of the stereotype of the geek, it is not uncommon to see representations of them in popular media. Whether it be in recent television productions (such as the *Big Bang Theory*), or in movies, new and nostalgic (*Napoleon Dynamite* and *Revenge of the Nerds*), or even in websites claiming to devote themselves to all things geek (www.geek.com). In this way, the concept of the geek has proven to be an enduring staple in the modern consciousness.

And yet, the idea of the geek has not been a static fixture. It has undergone an extraordinary evolution to the present era (see Engelhart, 2012 for an account). As the concept has matured, it has expanded to include its own unique conceptualizations of culture and community, developing into a rich tapestry of related ideological camps – or "imagined communities" – of like-minded individuals who identify as a geek and share similar values.

Ethnographic investigations of various geek culture communities have proposed a number of theories concerning the importance of participation in this historically stigmatized subculture (Tocci, 2009), often attending to the rationale for participation in these communities in spite of the attached stigma. This has often entailed exploring individuals' deep feelings of loyalty to, and belonging with, these communities in spite of their problematic nature. On the whole, reasons for participating in geek communities may be summarized as both an identification with the "geek ethos" – a set of values common to all geek cultures – and a desire to create an "ideal geek community" (Piña, 2018).

Therein, embedded as it is in the geek ethos, is a clear articulation of both the aspirational drive for creativity and the need for consistent engagement in creative activities. This is made plain in the writings of self-described geeks like those of Lars Konzack, who argued that "Geeks are incredibly creative minded. They like to contribute artistically to the geek culture, not just consuming it. The geeks don't just read comics, but they make their own drawings as well. The geeks are not just playing games, but try to make game content too" (2006, pp. 6–7).

Although creativity appears to be an ideal equally held in all aspects of the geek culture, this is not to say that it is equally instantiated in every sector of the culture or in every community. Creative behavior may look extraordinarily different, for example, between a group of older roleplaying gamers who meet on weekends and a group of younger schoolmates who share a love of computer programming and meet primarily through virtual media. Extant research has provided two primary vantages for understanding underlying relationships which may account for variation in creative expression, being continua based on: (1) age-related psychosocial development, and (2) avocational engagement in informal participatory cultures.

In the coming sections, these areas will be explored by attending to research which has highlighted the experiences which shape the creativity of younger adolescent geeks and the creative contexts of older geeks, as well as creativity as expressed relative to participation in fandoms and creative behaviors occurring as a consequence of participation in fan communities.

The Creativity of Adolescent Geeks

It is in approaching adolescence that the geek identity first seems to matter deeply for young people. This is likely the result of a host of psychosocial developmental changes that take place in quick succession, as peer group approval and the role of popularity become increasingly salient to young teens. In consequence, while the geek identity may bear some latent ideological stigma from cultural presentations of the stereotype among children, it is in adolescence where this burden is thought to be most acutely felt: Adolescent geeks are, to varying degrees based on their local community and educational context, subject to ostracism and harassment from their peers.

As such, the general presentation of peer communities of young geeks has a tendency to be relatively small, closely-knit, and semipermeable, with a supportive and nonconformist character. This is perhaps most lucidly exemplified in ethnographic works like that of Bucholtz (1999), wherein the author described a local "Bay City" high school group of young geeks, the "anti-club" entitled Random Reigns Supreme (1999, pp. 212–213). This group was small, consisting of only four core members and two peripheral participants, but despite its size, demonstrated a nimety of what the author described as "positive identity practices" – that is to say, activities and behaviors which built group identity by upholding a common set of "subversive" values, including an emphasis on the importance of "randomness" (replacing the traditional effort to emphasize more popular topics, like sports and clothing), as well as frequent displays of wit, knowledgeability, and intelligence (1999, pp. 214–218).

From examples like this, it is apparent that both the organization and composition of adolescent geek communities appears to have some influence on the creative expressions of participants. Piña (2018) found that contextually-embedded social characteristics of public schools, most especially peer support and attitudes toward academic performance, predicted associative differences in the "identity transition status" of young geeks, which, in turn, framed noteworthy patterns of variation in the domains of creative engagement, both in the quantity of creative efforts in those domains and in the perceived quality, or social recognition, of those creative efforts. Among students who had "embraced" their geek identity, for example, there were statistically significant comparative increases in the quantity and quality of scientific and mathematical creativity, whereas among students who had "normalized" their geek identity, there were notable differences in the quantity, but not quality, of artistic creativity (2018, p. 109).

These insights highlight the paramount importance of continuing to advance a diverse view of the experiences of adolescent geeks, and, additionally, of engaging young people in transformative dialogue about inclusiveness in geek culture venues. Given the growing awareness of the manner in which the stigma of being a geek is compounded by social factors affecting young women, cultural minorities, and especially culturally-diverse young women (Herrera, 2017), an unambiguous conclusion is that gate-keeping activities – actions designed to keep 'unwanted' or 'unworthy' individuals out of the geek culture (as in Reagle, 2015) – are harmful not only due to their effect of socially isolating vulnerable groups of adolescent geeks, but also in that they create conditions whereby the creative benefit of engagement with geek culture can be suppressed (Piña, 2018), and, indeed, where otherwise extraordinary conditions for burgeoning creativity may be exhausted by the thoughtless actions of a callous few.

The Creativity of Adult Geeks

Coming to describe oneself as a geek in adulthood can be seen as one of many developmental outcomes resultant from structuring one's identity throughout adolescence against the changing social realities of participation in the geek culture (see Pegg, 2012 for an autobiographical account). Young adult geeks in America – like many groups of young adults in the Western culture – tend to discover that, as they advance through adolescence, their peer culture is a product more of their own choice, and also that their ability to harness resources allows for some discretion in how they engage with geek culture activities. For these reasons, there is a context of recent access to relative cultural freedom that undergirds nascent understanding of the creative potential of adult geeks.

As such, much of the work comprising field of Geek Studies has framed contemporaneous notion of the adult geek to primarily one of three conceptual positions articulating these newly-conferred freedoms, these being positions on (1) the narrative of struggle against a historical stigma giving rise to an increasingly popular representation of the geek, (2) the value of the modern role of the geek identity as a facilitator of innovation, especially as it relates to technology and digital media, and (3) the troubling representation of the geek as a transgressive figure – a cultural misfit who engages in bizarre behaviors, often spurred on through connection to online forums.

Addressing the first of these three perspectives are works like those of Kendall (2011), and Claassen (2015) which concerned themselves with the representational evolution of the geek, both as applied to the popular culture, and as it illuminated the view that geeks have held of themselves in the midst of changing attitudes. Compellingly, both of these authors focused on a different artifact of the evolution of the geek culture as a means of interpreting the significance of the changing popular opinion of the geek: Kendall (2011) unpacked recent geek-centric media representations and the rise of “nerdcore” music while Claassen (2015) analyzed the effects of a rapidly-changing geek culture through the examples of movies, including *Ready Player One* and *Dodgeball*.

These works helped shape a central theme of the perspective: That, as Claassen (2015) posited, geeks now occupy an ambiguous and paradoxical position within the popular imagination, being somehow both “misfit” and “cool” simultaneously. The consequences of this condition are not yet widely understood, and there seems to be no real agreement in the significance of the transition. Kendall (2011), followed a continual argument tracing the enduring association of the geek identity with whiteness and hegemonic masculinity – in essence, casting a cautionary and critical light on the exclusionary cultural underpinnings of the geek stereotype, no matter the level of popular acceptance. On the other end of the spectrum, Claassen (2015) has advocated the more benign notion that the geek is becoming just another variety of popular, well-known identity.

A distinct element of the geek culture which has aided in its ascent in the popular imagination – and one which more immediately relates to the topic of creativity – is found in a second Geek Studies perspective that stresses the singular, and ever-growing, importance of technological and scientific development. Here, there are depictions of the geek as a “genius” (as in Tocci, 2009) who has the potential to contribute to human mastery of the world through the creation of scientific, as well as technological, and, to an odd level of specificity, computational innovations. Unlike the ambivalent view given earlier of the geek as a regular, albeit relatively niche, identity to be embraced and/or mocked, in this perspective, geeks are cast as the object of respect and admiration due to their ability to harness technical “wizardry.”

A salient observation of this strand of research is that, even though role of the geek is praised as a key to innovation, there remains a gap in knowledge of the mechanism by which participation in geek culture can be determined to actually facilitate such innovation – and, by proxy, creativity in the broader sense. This is to say that there is yet no strong theory or even competing theories of ‘geek creativity’, per se, but not to imply that no research on the topic exists, nor that there are no initial insights from which to work: Utilizing survey data, McCain et al. (2015), for instance, accumulated evidence to support the insight that individuals who more strongly identify as geeks concurrently demonstrate statistically significant increases in creative engagement, creative ideation, and positivity toward the concept of creativity (2015, pg. 27).

However, as perspectives of the innovative nature of geeks are refined, so too must society come to terms with the darker and stranger interpretations of geek culture. As creativity and nonconformity are deeply entwined (Runco, 2014), there is a natural basis for understanding consequent social implications: To the degree that geeks can be innovative, so too can they express themselves through oddball activities. And, in fact, there is an abundance of evidence for this tendency. From furies to therians, to bronzies, the support and acceptance for “misfits” availed of in the geek culture (as in Tocci, 2009) has provided a forum and structure to adult communities with personal, religious, and sexual expressions that may otherwise be considered transgressive in the dominant culture. And, while undeniably eccentric, these groups appear to be, more or less, harmless instantiations of the playfully transgressive character of passionate participation.

This “misfit” aspect of the geek culture can genuinely become a cause for concern, though, when it intersects with the advancement of harmful ideals and behaviors. Here, by way of pluperfect example, it is the community of involuntary celibates – “incels” – which has undoubtedly garnered the greatest attention. To date, participation in the incel community has been linked to acts of terroristic violence, the perpetuation of virulent racism and misogyny, and the promotion of suicidal ideation among its members. Given the seriousness of these actions, the question that consequently arises with regard to incels – and, more broadly, to all participants of the hate-fueled, anti-feminist “manosphere” (Ging, 2017) – is a fundamental one: What can be done? If incel communities reflect the deepest pain and resentment of the geek community, and that pain seems undiminished (and, in fact, exacerbated) by social advancements made by the geek culture at large, what future steps can be taken to ameliorate this very real and dangerous problem?

There are, as yet, no fully satisfactory answers to these questions. At best, current understanding illuminates that the hateful behavior of these individuals is most likely to be driven by persistent feelings of loneliness. MacDonald (2016), targeted this loneliness, as well as concomitant depression, as the root cause of negativity in the incel community, and argued that a combination of cognitive-behavioral therapy and social skills training may be most effective solution. It is perhaps possible, then, that one means of large-scale intervention might be to make use of existing social structures in geek communities, such as culturally intermediate “alpha geeks” (as in Piña, 2018), to advocate for such therapies, by, at a minimum, raising awareness of the importance of mental health in geek communities and receiving education on the topic. Through these means, informed geek spaces will also better express the qualities of creative climates, especially in advancing open-mindedness and support, as well as offering important resources to community members. It is left to future researchers, however, to determine the organization of such a program.

The Creativity of Fan Communities

An alternate, and complementary, approach to understanding the role of the geek culture as a support system for eliciting creative behavior can be found in examinations of interactional modes of topic-focused geek communities or “fandoms” (as in McCain et al., 2015). Here, unlike in the case for the psychosocial perspective in the Geek Studies, a widely applicable model for creative facilitation has been propounded: That engaged participation with an area of interest in the geek culture can elicit strong enthusiasm for an avocation, which in turn fuels the desire for creative expression. However, this unified perspective of a mechanism for creative participation does not imply that creative products and behaviors will be even remotely similar, and for a simple reason: Areas of geek interest can vary wildly encompassing, among other things, deep interaction with fantasy worlds and sci-fi settings, interest in computer technology and engineering, and other, obscure interests, all of which draw from different creative domains.

Due to the extraordinary diversity in fandoms, it is unlikely that a complete, exhaustive accounting of the creativity of all fandoms can ever be given. Rather, it may be of greater value to instead compare, at the broadest level, how these fan communities have historically engaged with their interests in two broad areas: Through the development of (1) fanart and through the development of (2) fanfic.

Creative efforts of the first type, those characterized by making use of geeky topics serving as inspiration for “fanart” creations (as in Manifold, 2013), have tended to demonstrate the ability to invoke emotional resonance in enthusiasts, to arouse curiosity and the pursuit of meaningful challenges, and to provide a basis for supportive participation in communities who share a recognition for the importance of each participants efforts. An excellent example of these elements converging exists in communities supporting the fanart of “costume play”, or “cosplay”, which is an artmaking practice involving the production of elaborate costumes representing fictional characters, most often drawn from depictions in popular video games, television shows, and manga. Through cosplay, essential artistic skills are practiced and affective attachments to the material are explored in a fluid manner within whole communities.

For these reasons, participation in cosplay communities, and, by extension, fanart communities categorically, has been promoted as a necessary supplement to formal education in the visual arts, with informal fan communities occupying a role as both avocational playgrounds and continued vocational training. This cooperative interaction among personal, playful, professional, and purposeful work in fan communities is especially significant in fanart communities working with digital media and programming – perhaps blurring a line between geek culture and the “maker movement” – whereby fans modify, or “mod”, digital assets, such video games and user interfaces, in an innovative process that Kücklich (2005) summarily dubbed “playbour.” Here, it is valuable to point out that many avenues of future research yet exist in the study of fanart and its many variant instantiation, as this type of participatory creativity appears to have expanded to encompass practices that deviate from a simplistic understanding of artistry as it may have been understood in previous eras.

But it is not through fanart alone that geeks may partake in simultaneous productivity and affective or semiotic participation. Fan communities also display a propensity to produce unofficial written works and performances as fictional extensions of their source material, a practice referred to as “fan fiction” or “fanfic” writing. Fanfic has a rich history and a perennially notorious reputation, being both the birthplace of new popular media, such as the *Fifty Shades of Grey* book series, as well as the origin of a not inconsiderable amount of homoerotic and fetishistic “slash” fiction. As with fanart communities, the creativity of fanfic communities is thought to stem from the highly collaborative nature of the culture. Fanfic, too, has many variant instantiations, with written works being translated as stage productions, movie script “remixes”, and fan poetry.

Ultimately, though, a key difference in the creative expressions of fanfic and fanart communities can be determined by considering the relative ease with which fanfic authors may undertake to innovate the systems and settings presented in written texts as a medium in themselves for creative discovery. In this sort of work, rather than deriving a new narrative, character, object, or event from fiction, an entire imaginary world is itself taken as the subject – a creative act known as “world-building” (see Wolf, 2014 for an in-depth discussion). Working from the world as a starting point, world-building can encapsulate generative activities like the formulation of constructed languages and the proposal of differing reality systems. This has been one of the hallmarks of creative individuals.

In geek communities, world-building is a traditional practice of certain writing groups and a tool of “game masters” who lead table top role playing gaming groups. Increasingly, too, world-building is manifest as transmedia storytelling and in the wider promulgation of participatory narratives. “Alternate reality games”, for example, offer an opportunity for geeks to play in a constructed world that pervades from the digital realm into the physical, fostering a special, strongly immersive experience within the interactive structure of the overall narrative.

There is a growing understanding that these storytelling experiences may be useful as a new type of creative learning environment, which in themselves may provide an otherwise unexplored vantage by which shed light on the evolutionary cycles within creative development (Velikovsky, 2014). This suggests that future investigations concerning of the creativity of fanfic communities may well be served by accounting for the manner by which these new media have influenced participants to create novel elaborations, not of single objects or ideas, but of complex systems and complete imaginary worlds.

Introduction

Consider the following historical personalities: Napoleon Bonaparte, Abraham Lincoln, Isaac Newton, Marie Curie, Leo Tolstoy, Leonardo da Vinci, and Ludwig van Beethoven. What do they have in common that sets them apart from the rest of us? Several answers are possible, but two perhaps stand out. First, all can be considered geniuses of some kind, whether military, political, scientific, or artistic. Second, all can be said to display greatness in their chosen domain of achievement. Thus, Napoleon was a great general, Lincoln a great president, Newton a great scientist, and so forth. In these examples, genius and greatness appear to go together. Yet do they always have to correspond? Can genius exist without greatness or greatness without genius? It is the purpose of this entry to examine the conceptual connection between these two constructs. Discussion begins with their respective definitions, and then examines the convergences and divergences implied by these definitions. Although often used interchangeably, the two terms are by no means equivalent.

Genius

The concept of genius has undergone a substantial change over the course of history. The word originated in Roman times. According to Roman mythology, each man was born with a genius that represented a kind of guiding spirit or guardian angel. A man's genius is what made him distinctive – and exerted some influence over his fate. Although the parallel tutelary spirit for women was a “juno,” this gender-differentiated usage did not survive to modern times. Interestingly, not just individuals had a genius. Particular places might have genius loci that served as protective spirits. And a Roman clan, caste, or group of families could also have a genius. Although the connection is not completely secure, the Latin word may be related to the Arabic “jinn,” often translated into English as “genie.”

Over time, genius became dissociated from the spiritual world. Instead, it became something highly characteristic of a given person, especially with respect to some unusual ability or inclination. Someone could have a genius for making friends, for example. In line with this usage, anyone could have a genius because genius is what defined one's individuality. But since the Renaissance, genius began to acquire a more restrictive meaning. As a result, only an elite subset of the human population could be said to have genius. In particular, a person could only be considered a genius if he or she exhibited exceptional intellectual or creative power. Uniqueness or individuality was insufficient.

At first, the emphasis seemed to have been placed on the creative powers. For this reason, perhaps, genius was initially confined to artistic domains of achievement. William Shakespeare and Michelangelo Buonarroti could thus be considered geniuses. Scientific creativity, by comparison, required no genius because science relied solely on a method that could be taught or imitated. For

This article is an update of D.K. Simonton, Genius and Greatness, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 564–570.

instance, Immanuel Kant argued, in his *Critique of Judgment*, that even a scientist as great as Newton could not be considered a genius because someone could theoretically learn to do what he did. Artistic geniuses, in contrast, invent their own rules, unconstrained by logic and fact. Nonetheless, eventually genius came to be found outside of the arts, including in the sciences. Indeed, after a while it became reasonable to speak of military genius, political genius, and the like. Sometimes the term even became overextended. Galton's, 1869 *Hereditary Genius* includes athletes along with generals, scientists, philosophers, artists, and composers.

These etymological developments lead to the most critical question: How can genius be given a definition suitable for scientific research? Stated differently, is it possible to devise a definition of genius that supports precise measurement? The answer is affirmative but plural. Researchers have tended to use two rather divergent definitions of genius, namely, the historiometric and the psychometric.

Historiometric Definition

Galton was the first to define genius in terms of historical impact. A genius was someone who had acquired an extraordinary reputation for culturally valued achievements. This reputation was first established with contemporaries but was later consolidated by the posthumous appraisals of posterity. Given sufficient time, the judgment of an individual's contributions to civilization should become reasonably stable. Certain reputations will have withstood the "test of time" whereas others will have "fallen by the wayside." The question was then how to assess whether or not a particular individual could claim sufficient reputation to be counted as a genius.

Galton's solution to this problem was to adopt a crude eminence measure [see Eminence]. A person who was featured in a major biographical dictionary had a *prima facie* justification for being considered a genius. An alternative solution was proposed by Galton's contemporary Alphonse de Candolle (1873), who introduced awards or honors as the criterion of distinction [see Awards]. More specifically, Candolle studied scientists who were sufficiently illustrious to earn election to a prestigious scientific society. Galton later endorsed this criterion as a reasonable alternative to his original measurement strategy.

Even so, both of these measures had a drawback: They did not admit of degree. Geniuses can differ in the magnitude of their genius. Not all persons with entries in a biographical dictionary are equally eminent. Galileo Galilei certainly surpasses Evangelista Torricelli, just as Fyodor Dostoyevsky outshines Aleksandr Kuprin. Similarly, not all recipients of a given honor or award are of equal standing as geniuses. Albert Einstein received the Nobel Prize for Physics one year after the same award was bestowed on Charles Edouard Guillaume. Whereas the former laureate revolutionized our conceptions of matter, light, space, time, and gravity, the latter laureate merely discovered some anomalies in nickel steel alloys.

The first researcher to offer a quantitative rather than qualitative measure of genius was James McKeen Cattell. In 1903, he ranked the 1000 most eminent creators and leaders of Western history based on the amount of space devoted to each luminary in standard reference books. According to his sources, the most space was devoted to Napoleon and Shakespeare, the least to Barthélemy Prosper Enfantin and François-Noël Babeuf. Later investigators refined this approach, especially Frederick Woods, who was the first to refer to such measures as historiometric [see Historiometry].

Cattell also introduced an alternative method for the historiometric definition of genius: expert surveys. He would ask experts to evaluate the relative impact of eminent scientists. This approach has also been used frequently to assess the differential influence of achievers in a variety of domains, including classical composers and US presidents.

The above two historiometric definitions are not equivalent. Space measures tend to have much more skewed distributions than do expert evaluations. Even so, they correlate very highly, the top figures by one assessment tending to be pretty much the same as the top figures by another assessment. Just as important, historiometric judgments tend to be highly stable across historical time, even after the passage of a century or more.

Psychometric Definition

The historiometric definition of genius is clearly sociocultural rather than psychological. Reputation is irretrievably contingent on the opinions of others. Scholars have to decide how much space to assign entries in biographical dictionaries, and experts have to assess the relative impact of various contributions. Nevertheless, Galton believed that an achiever's reputation was directly related to his or her personal qualities. In particular, he attributed genius to high natural ability. The latter was a complex concept that included intelligence, energy, and motivation. Even so, it is clear that Galton viewed intellect as primary. Human beings varied greatly in natural ability, and this variation was quantitative rather than qualitative. That is, each individual could be placed on a continuous scale with the least able at the bottom and the most able at the top. In addition, Galton introduced an important innovation: the concept of the normal distribution, as described by the "bell curve." Although Adolphe Quételet had shown that many physical characteristics, such as weight and height, were normally distributed, it was not until Galton that psychological attributes were said to have the same distribution. He went even further by specifying that geniuses represent the upper tail of this normal distribution. That is why geniuses are so rare.

Unfortunately, at the time that Galton advanced this concept of genius, no instruments existed by which he could directly measure natural ability. So he was obliged to devise his own instruments, eventually producing a large number of "anthropometric" measures. These assessed individuals on visual and auditory acuity, reaction times, breathing power, strength, height, and weight – attributes that do not seem to have an obvious link to natural ability. In fact, these measures were later shown not to correlate with anything that would be associated with intelligence, even less with genius. As a consequence, Galton's instruments could not provide the basis for a psychometric definition of genius.

The needed measures came from an unexpected quarter. In the early 20th century, [Alfred Binet and Théodore Simon \(1905\)](#) devised an intelligence scale that assessed a child's mental age. [William Stern \(1914\)](#) later conceived the idea of dividing the mental age by the chronological age and then multiplying the result by 100 to yield an intelligence quotient, or IQ. Not long after, [Lewis M. Terman \(1916\)](#) adapted the Binet-Simon for use with English participants, implementing Stern's concept of the IQ. In the early 1920s Terman applied the resulting Stanford-Binet Intelligence Scale to a large sample of young children. Those with IQs of 140 or more were then subjected to an intensive longitudinal investigation. The study was published in a series of volumes under the title *Genetic Studies of Genius* ([Terman, 1925–59](#)). The criterion of IQ 140 thus became the psychometric definition of genius. This cut-off even found its way into some standard dictionaries.

Of course, such a threshold is necessarily arbitrary. It defines those individuals whose IQs are in the top 1% of the general population. Certainly alternative cut-offs might also be justified. Mensa, the organization for high-IQ people, requires that a member only be in the top 2% of the population, whereas membership in the Triple Nine Society demands a score in the 99.9th percentile. Even more extreme, the Mega Society sets the IQ requirement at the 99.9999th percentile! Because standard intelligence tests do not yield scores high enough, candidates for membership must take specially designed tests.

Given the psychometric definition of genius, the person with the highest recorded IQ would be considered the world's greatest genius. Marilyn vos Savant was once listed in the *Guinness Book of World Records* as having that distinction, with a putative score of 228. Although both the claim and the score are controversial, she does illustrate an important point: Psychometric genius does not always correspond to historiometric genius. Since 1986, her chief claim to fame has been the column "Ask Marilyn" that appears each Sunday in *Parade* magazine. Here she answers questions and solves puzzles posed to her by the column's readers. She has not yet made a single contribution that would make her eligible for the distinction of being called a genius in the historiometric sense. Her situation can be contrasted with that of her husband Robert Jarvik, who attained some degree of eminence as the inventor of the Jarvik artificial heart. Stated differently, Jarvik's claim to greatness is probably higher than vos Savant's even if the latter has the higher IQ.

Greatness

The concept of greatness is strongly associated with what was once called the Great Man Theory of History. In this view, history is essentially equivalent to the biography of a few "great men" or "heroes." This theory is often credited to the British historian Thomas Carlyle, who expounded the position in his 1841 book *On Heroes, Hero-Worship and the Heroic in History*. He devotes considerable attention to such historic figures as Napoleon, Muhammad, Martin Luther, Jean-Jacques Rousseau, and Shakespeare, seeing them as decisive agents of civilization. Supposedly, the world we live in would be decidedly different if these individuals had died in the crib. A more recent illustration of this theory can be found in [Hart's \(2000\)](#) book *The 100*, which purports to rank "the most influential persons in history." The top figures on his list are Muhammad, Newton, Jesus Christ, Buddha, and Confucius. A glance of the complete 100 reveals that every one of these influential figures can be assigned to one of two categories of greatness: outstanding leadership and exceptional creativity. However, it must be recognized that another guise of greatness exists that cannot be included in either of these two categories, namely, prodigious performance. Below we examine all three forms.

Outstanding Leadership

Leadership has been defined many different ways. Some of these definitions have greater scientific utility than others. On the one hand, we might identify leadership with some mysterious property that only certain great persons possess, such as charisma, dynamism, or magnetism. These highly romantic conceptions of leadership have immediate appeal, capturing as they do some popular myths about great leaders. However, such notions do not have much precision. Accordingly, these ideas do not lend themselves to measurement, and if scientists cannot measure an attribute, they cannot really study it.

Hence, leadership researchers tend to adopt a much less romantic conception of the phenomenon. Given a group of individuals, leadership is defined according to the magnitude of influence a given group member exerts over group problem solving, decision making, or cohesiveness. Although the person who displays the most impact is often called the group leader, groups can have more than one leader, and often do. For instance, one leader might be a "task specialist" while another would serve as the "social-emotional specialist." Where the former would focus on group decision making or problem solving, the latter would concentrate on maintaining group morale or cohesiveness. Naturally, the best leaders would exhibit the capacity to accomplish both ends [see Teams].

Defining leadership in this way leads quite naturally to a definition of "great leaders." The groups over which great leaders exert their influence are much larger, and the magnitude of that influence is much greater. The groups are whole nations, even civilizations, and the influence takes the form of new religions, laws, reforms, institutions, military victories, or territorial conquests. It is no accident that some of the highest ranked luminaries in *The 100* are religious leaders: Their impact often affected millions of people not only in their own time but also for centuries after their death.

Exceptional Creativity

The creative individual is usually defined as someone who can generate ideas that are both original and adaptive. However, both criteria are quantitative rather than qualitative variables. There are degrees of originality and degrees of adaptiveness. An idea might seem original to a person even if it is not original to others. And an idea might work for a person without working for others. For this

reason, it has become standard practice among researchers to distinguish between “little-c” and “Big-C” creativity [see Everyday Creativity]. The former involves the low levels of originality and adaptiveness that are sufficient for everyday life. An example might be a new recipe in response to some missing spices. The latter entails high levels of both factors. The levels may be so high that the ideas are deemed original and adaptive by many others, and perhaps even by a whole discipline, society, or civilization. Big-C creativity almost invariably results in the creation of a specific product, such as a poem, play, novel, painting, sculpture, design, composition, patent, monograph, or journal article. Furthermore, it is not enough to create a concrete product; it also must have impact. For example, a poem must be frequently anthologized, a composition must be often performed and recorded, and a scientific article must be cited by many other scientists. Indeed, at the highest level of creativity the product may become labeled as a masterwork or masterpiece.

It should be evident by now that Big-C creativity bears a striking conceptual relation with leadership. Such creators are in effect leaders, and the greatest creators are the greatest leaders. The main difference is the “group” that is the object of influence. A great filmmaker exerts influence over movie audiences and critics – and over fellow filmmakers as well. Moreover, the impact of the greatest creators, like that of the greatest leaders, withstands the test of time. Newton was listed among the most influential creators because his contributions to mathematics and physics shaped the course of history. Even Einstein was profoundly influenced by Newtonian physics. Einstein’s special and general theories of relativity only acquire importance in the context of Newton’s mechanics. One cannot launch a scientific revolution without having an established paradigm against which to revolt [see Paradigm Shifts].

Notice that Newton and Einstein exemplify another feature of truly great creators: Their impact extends beyond the specific domains to which they contributed. Both have produced ideas that became part not just of the larger intellectual community but also popular culture. The story of Newton discovering gravity while sitting under an apple tree and Einstein’s famous equation $E = mc^2$ are known to people who might never have had a course in physics.

Prodigious Performance

It was mentioned earlier that Galton included athletes among the “geniuses” in his 1869 *Hereditary Genius*. Specifically, he examined both oarsmen and wrestlers! Although it seems to be stretching the concept of genius to apply it this way, no reservations are required when we speak of greatness in sports. Athletes who receive Olympic gold medals, win world championships, or hold world records can certainly earn this status. Thus, in this sense, we can say that Michael Jordan was a great basketball player or that Joe Montana was a great quarterback. Furthermore, it is obvious that the epithet “great” can be legitimately assigned to other exemplars of prodigious performance. For example, we certainly speak of greatness in chess, and the term is no less applicable in the performing arts including acting, dancing, singing and instrumental performance. In general terms, if supreme performance in a given talent domain is recognized with trophies, prizes, or awards, it becomes appropriate to view the achievements as signs of greatness [see Awards].

In the case of outstanding leadership and exceptional creativity we add the proviso that the person must exert sufficient influence to earn the ascription of greatness. The same requirement might be attached to prodigious performance as well. To be great, the individual must inspire others in the same talent domain. For example, many violin and piano virtuosos have been inspired by the great Jascha Heifetz and Vladimir Horowitz, respectively. In sports, certain world records set by earlier great athletes can inspire their successors to strive to attain an even more impressive greatness. With the advent of audio and video recordings, it has become possible for somewhat ephemeral forms of achievement to provide inspiration for subsequent generations.

But must we consider all forms of prodigious performance to count as instances of greatness? There are certainly cases where we might wish to withhold the appellation. Should we count serial killers? Should greatness be ascribed to individuals who manage to make it into the *Guinness Book of Records* for feats such as stringing together the longest chain of paperclips in a 24-h period?

Convergence

It is possible to provide a convergent definition that combines the concepts of genius and greatness. The best place to begin is Kant’s definition of genius, which combines some of the features of the earlier definition of creativity with some of the aspects of Galton’s historiometric definition of genius. Kant said that geniuses must generate a product that is both original and exemplary. A product is *original* if it does not depend on the *imitation* of others, and it is *exemplary* if the product is so striking that it becomes an object of imitation by others. Although Kant confined his definition to artistic creativity, the restriction can be relaxed. Contrary to what Kant argued, Newton’s *Principia Mathematica* can be considered both original and exemplary. The work provided a new model for doing physics that dominated the field until the early 20th century. Even if Newton had to learn a lot of mathematics and science to conceive his masterpiece, the resulting product was by no means imitative. The work advanced well beyond its influences. At the same time, Kant underestimated the role of “imitation” in artistic creativity. Contrary to what he maintained, talent alone does not suffice to produce works that are both original and exemplary. Even artistic creators have to devote a considerable amount of time to mastering the necessary knowledge and skills. In fact, research has shown that it normally takes about 10-years of extensive learning and practice before anyone acquires sufficient domain-specific expertise to make superb contributions to a given domain (Ericsson and Pool, 2016). This 10-year rule even applies to child prodigies like Wolfgang Amadeus Mozart.

Indeed, we can contend that a product cannot be viewed as a work of genius unless that product represents a domain in which the 10-year rule applies, at least as an approximation. This requirement then rules out many of the achievements that populate the *Guinness Book of Records*. Whoever first came up with the task of stringing paperclips together in a 24-h period was certainly original, and the task later became exemplary, at least in the sense that the accomplishment inspired imitators who hoped to get their names in the record books. Yet it is patently true that the 10-year rule does not apply. It does not take a decade to learn how to form paperclip chains. Ten minutes is more than enough practice. Hence, even the originator of the Guinness category cannot be identified as a genius.

The preceding stipulation suggests another useful requirement. It is not just a matter that chaining paper clips requires no vast domain-specific expertise. It is also the case that it requires no exceptional intelligence to acquire and manifest that expertise. Many of the unusual feats in the record books do not require any more than an average intelligence even if they require more expertise than paperclip chaining. This observation certainly holds for most of the events that earn Olympic medals. To become a champion in shot put no doubt demands tremendous skill that is contingent on considerable practice, physical talent and dedication. Still, it is unlikely that shot putters must be extremely intelligent to attain mastery of the sport.

Therefore, we may add the requisite that genius can only be displayed in a domain in which expertise acquisition and manifestation presume an intellectual power far above average. This intellectual power does not have to be of the variety assessed in the typical IQ test. It could even represent a more specialized ability, as represented by one of [Howard Gardner's \(1983\)](#) multiple intelligences [see Multiple Intelligences]. Einstein's expertise acquisition would then have a different intellectual foundation than Pablo Picasso's or Martha Graham's. Yet the fact would remain that the domain-specific expertise that they acquired could not be attained and demonstrated by the average person on the street. Not everyone has the intellectual wherewithal to acquire and exhibit superlative mastery of physics, painting, or choreography.

By this point, we have said that genius requires the generation of original and exemplary products within a domain that presupposes the acquisition and manifestation of an intellectually demanding expertise. Such a conception would definitely apply to every major domain of exceptional creativity, whether scientific or artistic. Moreover, if the concept of products is broadened to encompass the principal acts of generals, politicians, diplomats, legislators, judges, and the like, then the same definition works for extraordinary leadership. As a case in point, Napoleon's battlefield tactics can be judged as both original and exemplary – to such a degree that his tactics became the objects of study in military science. The definition can also be extended to certain types of prodigious performance. Undoubtedly, chess champions who devise original and exemplary tactics would be considered geniuses. The same might hold for violin virtuosos who come up with original and exemplary interpretations of masterworks in the classical repertoire. Athletes in certain sports may also qualify if (a) their skills required a high degree of intellectual power and (b) their accomplishments proved both original and exemplary. An example might be a player in a team sport whose prodigious performance permanently changed the nature of the game.

Nonetheless, this inclusive definition might seem too inclusive. After all, might not a "criminal mastermind" count as a genius if the crimes displayed domain-specific expertise, intelligence, originality, and inspired numerous imitators? Although the answer would have to be affirmative, given the conditions, the criminal would be considered a genius of a special type, namely an "evil genius." [see *The Dark Side of Creativity*] More critically, we would not assert that the hypothetical individual exhibited greatness. That ascription cannot be applied because greatness presumes that the products of genius fulfill widely shared values. That is, the achievements represent contributions to society to a whole and not to some small group or individual that has what might be deemed a parasitic relationship with the larger society. Accordingly, the person credited with the accomplishment can be broadly taken as a role model for many others to follow. Stated differently, the genius who attains genuine greatness can be proclaimed as a sociocultural paragon – a person who exemplifies what is commonly taken as the best and the brightest. He or she inspires nearly universal admiration. Consequently, their portraits or images of their accomplishments more often end up on postage stamps, T-shirts, and even cartoons. The cream of the cream will have monuments built in their memory, such as the Washington, Jefferson, Lincoln, and Roosevelt memorials in Washington DC.

In the earlier discussions of genius and greatness, it was noted that these are quantitative variables rather than qualitative attributes. The same observation applies to the convergence of genius and greatness. The greatest geniuses are those who generate the largest number of original and exemplary products or acts that are widely admired as lasting contributions to civilization. For this reason, one-shot or one-idea achievers receive much less acclaim than those whose lifetime of notable achievements cannot help but provoke awe. Pachelbel's Canon in D is certainly a very pleasant work, but it is a rather small peg to hang a reputation on in comparison to all the masterworks generated by Johann Sebastian Bach. Worse yet, Pachelbel's best cannot really compare with Bach's best, so the former is overwhelmed by both quantity and quality. Necessarily, then, Bach must be credited with more genius and greatness than Pachelbel. This same contrast is applicable to great leadership and performance as well. Union General George Meade established his reputation for his defeat of Confederate General Richard E. Lee at Gettysburg, yet Meade's lone achievement pales in comparison to the multiple Union victories under General US Grant.

Divergence

The previous section just outlined how genius and greatness might be viewed as converging on the same exemplars of exceptional creativity, outstanding leadership, or prodigious performance. This integration began with Kant's assertion that genius produces works that are original and exemplary, and from there added domain-specific expertise, high intelligence,

productivity, and sociocultural value. Yet it must be recognized that this synthesis came with a price: Unlike the psychometric and historiometric definitions of genius, the convergent definition of genius and greatness does not lend itself to direct measurement. Some of the components of the definition are too elusive or vague, such as sociocultural value. For that reason, we have to ask how psychometric and historiometric genius compare with greatness.

Psychometric Genius Versus Greatness

We have put forward that bona fide genius demands sufficient intelligence to enable a person to acquire and manifest domain-specific expertise. So what is the minimum level of intelligence that would suffice? Creativity research has often suggested a threshold IQ of 120. If we take this figure to apply to various intelligences rather than just that intelligence tapped by IQ tests, then it should be apparent that a genius-level psychometric IQ is not necessary. Being intellectually gifted should be sufficient. Even so, this threshold must undergo two reservations.

First, different domains of achievement seem to have distinct lower bounds to the amount of intelligence required. Among leaders, military leaders appear to require less raw intellectual power than do political leaders, and less intellect is demanded to become a poet than a philosopher (Simonton and Song, 2009). In some forms of leadership, in fact, the relation may assume a curvilinear form so that an IQ beyond an optimal level will exert a negative effect (Antonakis et al., 2017).

Second, whatever the threshold level required for a particular domain of achievement, higher levels of appropriate intelligence are associated with higher levels of greatness. This positive relation was first demonstrated in Catharine Cox's classic 1926 study of 301 geniuses in which she estimated IQ scores using historiometric methods (see Historiometry). Moreover, the association has been replicated in several subsequent studies. For instance, it has been shown to hold for United States presidents, European monarchs, and eminent African American creators and leaders (Simonton, 2009).

The upshot is that psychometric genius has a weak but positive connection with greatness.

Historiometric Genius Versus Greatness

One would think that historiometric genius would come much closer to greatness than does psychometric genius. Where the latter is predicated on a test score of some kind, the former is based on actual achieved eminence, as gauged by historiometric measures [see Eminence, Historiometry]. In addition, it would seem that a luminary cannot attain eminence without producing something that satisfies the criteria that we have laid out for greatness. However, various other factors can undermine the degree of correspondence between historiometric genius and authentic greatness.

In the first place, individuals sometimes attain not fame but infamy. Not every person who makes it into the history texts, biographical dictionaries, or encyclopedias is placed there because they affirm certain sociocultural values. On the contrary, they are included as examples of what not to do – individuals to be eternally derided and damned. Benedict Arnold, John Wilkes Booth and Grigori Rasputin are illustrations. Significantly, one empirical study of 342 European monarchs looked at the relation between a ruler's eminence and his or her assessed morality or virtue. The relation was defined by a U-shaped curve. The most eminent were either highly moral or virtuous (the famous) or highly immoral (the infamous). In the history of England, a "bad king" like Richard III is about as well known as a "good king" like Henry V. A parallel pattern is seen in the United States presidency. Both good and bad presidents are better known than run-of-the-mill chief executives are, particularly when the failed administration resulted from a major scandal. Richard M. Nixon attracts more attention in the archival records than do many other two-term presidents.

Even worse, sometimes a person may attain distinction for reasons that have nothing to do with their actual achievements, good or bad. Shakespeare once wrote, "Some are born great, some achieve greatness and some have greatness thrust upon them." The first and last of these three alternatives present the biggest concern. A significant proportion of eminent personalities born prior to the 20th century were members of royal or aristocratic families. Even if some of these "blue bloods" eventually ended up being the agents of worthy deeds, and perhaps even works of genius, a large proportion entered the history books through an accident of birth. Even if royalty and the aristocracy are on the wane, that is no longer the only biological route to fame and fortune.

The third of Shakespeare's three alternatives is perhaps the most interesting. Sometimes people do score high on historiometric genius because of events or circumstances that thrust greatness upon them in adulthood rather than at birth. To illustrate, United States presidents who are assassinated in office are more likely to go down in history as great presidents – despite the fact that there is absolutely no evidence that they are better leaders. Similarly, European monarchs who suffer a violent death – by whatever means – are more eminent than those who die peacefully. Although such arbitrary influences are most conspicuous in leadership domains, they appear in creativity as well. Sometimes it is just a matter of being at the right place at the right time. Karl Guthe Jansky, an engineer for Bell Labs, was assigned the task of investigating the source of static that disrupted transatlantic voice communications via short-wave frequencies. Having shown that source of interference came from the center of the galaxy, he inadvertently became the founder of radio astronomy. Had his employers assigned him a different job, he would have been denied the opportunity to make the discovery, and someone else might have become the field's founder. Instances of utterly capricious serendipity are all too common, introducing an element of luck in historiometric indicators of genius.

Hence, once more, the association between historiometric genius and greatness is positive but weak.

Conclusion

Genius and greatness are both highly praiseworthy and intimately linked concepts. And both are closely connected with creativity. When we speak of creative geniuses and great creators, the distinction between the two becomes imperceptible. At that convergence, we can talk of individuals who generate works both original and exemplary in domains that presume that exceptional intelligence had been relegated to the acquisition of domain-specific expertise. Even though both constructs are also related to eminence, the relationship has some unpredictable ingredients that render it more ambiguous. Eminent creators need not be identical to creative geniuses or great creators. When we choose to incorporate psychometric IQ into the mix of concepts, the result is even more complex and ill defined. At present, it is impossible to determine whether the ambiguities can be resolved with additional empirical research. Perhaps the problem is more logical than empirical. The concepts of creativity, intelligence, eminence, genius, and greatness may need analyses that are more refined before their overlapping meanings can be precisely delineated.

Introduction

Both creativity and giftedness are seen as the driving forces that push human civilizations forward. It is not a surprise that scholars who wrote on the history of creativity and those on giftedness both refer to the Sputnik Era as a turning point. This is a specific time in which the need for creative thinking and gifted education was felt most deeply by Americans, which fueled the interest, funding, and scholarship around these two related disciplines.

The link between creativity and giftedness has intrigued many scholars in different fields for decades. Creativity has been one of the most frequently researched topics in gifted education. Dai et al. (2011) found that creativity was one of the four main research topics in gifted education between 1998 and 2010. As of October 22, 2018, the PsycINFO database yielded 2441 publications for the combination of the abbreviated keywords “gifted*” and “creativ*”, and showed a steady increase on these topics across decades. However, the lack of agreement on definitions of creativity and giftedness beclouds the nature of the relationship between two constructs. There is a consensus that they are neither perfectly overlapping constructs nor totally unrelated. Treffinger (2004) proposes 5 themes that are expository grounds of the relationship between creativity and giftedness:

Definition. Attempts to define these two constructs resulted in the curiosity of how these two concepts are related to each other. Although there are several theories on creativity and giftedness, it is accepted that cognitive, non-cognitive and contextual factors play critical roles in both of them. This agreement gave rise to multiple links between creativity and giftedness.

Characteristics. There are some indicators that both giftedness and creativity share in common which people are able to manifest in genuine ways. They might be seen in different ways at various times involving different styles. Treffinger also pointed out a shift from “level” approach to “style” approach for both concepts. In other words, the way you express your creativity is more prevalent than how much creative you are. This variety of expressions also implies that these common characteristics can be improved and open to development.

Justification. The importance of giftedness and creativity has become more prominent in education. Many studies have shown the value of creativity in life and work. In addition, recent theories of giftedness viewing creativity as a component of giftedness expanded the scope of giftedness. The new paradigm of giftedness emphasizes the importance of inclusive definitions, diverse skill-sets and a multifaceted identification process in gifted education. Thus, the inclusion of other factors such as creativity or task commitment makes giftedness more integral to education. As a result, teaching creativity in education help students demonstrate their gifted behaviors and equip them better for the requirements of life and work.

Assessment. Both giftedness and creativity can be measured in different ways. No single score provides a comprehensive measurement. The accuracy of assessment is enhanced with the use of multiple sources. Improvement of assessment tools is a key to developing a better understanding and examination of giftedness and creativity.

Nurture. Creativity and giftedness can be improved. Although changeability of giftedness may be controversial when giftedness relies solely on a single factor such as intelligence, recent views on giftedness agree that multiple factors play roles in expressing giftedness. For instance, in Renzulli’s Three Ring Model, higher task commitment or creativity is associated with higher level of giftedness. There are many studies that examined how creativity and giftedness may be supported through programs and interventions, some of which are discussed below. It is noteworthy that nurturing the context or climate can result in improvement in creativity and giftedness.

Evolution of the Concept of Giftedness

Early definitions and conceptualizations of giftedness relied on high intelligence as the major or sole criteria. This brought about a heavy, if not unique, emphasis on IQ tests as the major criteria of identification. Dai (2016) called this dichotomous view of

giftedness (gifted vs. non-gifted) which rests on IQ testing and other assumptions of general intelligence as the Gifted Child Paradigm. This paradigm which is based on categorization (gifted vs. non-gifted), homogeneity and permanency of giftedness gave rise to some concerns such as elitism and inequality because only a small proportion of students could have access to advanced learning opportunities. Diversity and richness of human potential were frequently ignored in this era. Even though Dai (2016) argued that this paradigm still exists, recently, there has been an agreement that giftedness should be explained with multidimensional approaches, rather than with a single focus or measurement. This agreement led to a paradigm shift from overemphasis in general intelligence to talent development as a complex developmental pathway that takes various domains and social and psychological factors into consideration. Thus, contemporary views of giftedness are more dynamic and socially constructed. Some even proposed the term “outstanding talent” instead of “gifted.”

In contemporary research and scholarship, giftedness is no longer considered a fixed state of being but a developmental set of behaviors. For example, Piirto's (2011) Pyramid of Talent Development explains the development of talents in any domain needs to be supported at many levels by different factors including genetics, personality characteristics, cognitive traits, talent, and vocational and environmental factors. Environmental aspects include home, school, community, gender, and chance.

Similarly, Hong and Milgram (2011) described three main factors that shape the talent development in their theory, Comprehensive Model of Giftedness and Talent (CMGT): cognitive ability, personal-psychological attributes, and environmental-social factors. Cognitive abilities involve analytical and creative thinking whereas personal and psychological factors include motivation, interest, and biological ability. Environmental and societal factors consist of school, society, or family. Based on these factors, talent is developed in two distinct types at various levels: expert talent and creative talent. Expert talent involves more analytical and practical thinking whereas creative talent is represented by generating new and original solutions to problems in a domain.

It is now clear that giftedness is no longer seen through a positivist perspective and domain-specific models have become favored in the field. The new trend is a social constructivist approach. Talent is defined, invented and then invested in by society. This is a more inclusive, diverse, equitable and comprehensive stance than the earlier concept of giftedness.

Creatively Gifted

Broadening conceptualization of giftedness resulted in the inclusion of creativity in the definitions and models of giftedness. This went so far that some researchers viewed creativity as the foundation of giftedness. Runco (1993) stated that creative potential is one of the most critical commonalities among the various domains of giftedness. According to Winner (2000), creativity is an essential component of giftedness within any domain.

Some claim that creativity is the final stage of giftedness after gaining excellence. For instance, Subotnik and Jarvin (2005) proposed that cognitive abilities are necessary but insufficient to reach the highest level of a talent which requires productivity and creativity. This proposition is also consistent with Bloom's revised taxonomy, in which creating is the highest of form cognition. According to this revision, creating is superior to other cognitive operations such as remembering, understanding, applying, analyzing, and evaluating.

Some researchers view creativity as a type of giftedness. Creative giftedness is defined as a superior ability to generate ideas, solutions, behaviors, and insights that are novel and worthy in a specific domain or several domains. On the other hand, such a person may or may not show superiority in other talents and abilities. This is an important point because noticing the creative ability may be difficult when other talent areas are not obvious. Creative giftedness may need to be complemented by intelligence in order to adapt to the environment or new situation. As Kim and his colleagues underline that “Creatively Gifted Students Are Not Like Other Gifted Students” in their book's title. This type of giftedness can be disregarded during the identification process because those who are creatively gifted have some different traits than other gifted types. For instance, academic giftedness is associated with convergent and logical thinking whereas creative giftedness is related to divergent and associative thinking and involves a high level of novelty and originality in their ideas. Moreover, these students may have characteristics such as independence, autonomy, and challenging the status quo, assumptions, and authority. It is likely that these may be perceived as negative traits in the school environment where discipline and classroom management are a priority. Therefore, some highly creative students may never be considered for referral to gifted programs as such traits may cast a shadow over their creative potential. In fact, some researchers (e.g., Westby and Dawson, 1995; Scott, 1999) indicated the possibility of a hidden bias against creativity characteristics among teachers.

This line of research is important because gifted education programs may unknowingly embrace a “schoolhouse giftedness” approach rather than “creative/productive giftedness” as Joseph Renzulli warned. Schoolhouse giftedness includes students identified by conventional IQ tests who have exceptional skills in academic giftedness. This form of giftedness is often demanded, appreciated, and emphasized in schools. Creative/productive giftedness refers to the ability to produce original and useful work. Children may be considered gifted as a result of their academic success whereas adults are seen as gifted based on their creative products. This distinction seems to explain why some children or adults fail to be identified as a gifted. Programs for gifted are best suited to serve schoolhouse giftedness leading creative individuals to be omitted from gifted programs.

Sternberg and Lubart (1993) argued that creativity involves different cognitive, personality, motivational and environmental aspects. They argued that creativity is more important than academic performance for the development of societies and proposed six resources that give rise to creative giftedness: intellectual processes, knowledge, intellectual style, personality, motivation, and environmental factors. Creative giftedness rarely occurs because these factors must interact effectively. Educational systems need to focus on these resources to develop creativity in children.

Milgram (1990) made a case that cognitive abilities don't correlate with real-life creativity and that creativity was a better predictor of life accomplishment than intelligence. In her 4×4 Model, giftedness has four different categories, two relating to aspects of intelligence (general intellectual ability and specific intellectual ability) and two to aspects of creativity (general creative thinking and specific creative talent). She also sees giftedness as a result of the interaction of cognitive, socio-personal, and cultural factors. It should be underlined that her model views creative thinking as a distinct form of giftedness.

Winner (1996) stated that few gifted children become creative adults. This might be because giftedness, as conceptualized without creativity, does not necessarily lead to future creative productivity. Creatively gifted students need more attention and opportunities to develop their specific skills such as music, mathematics or art.

Creativity in the Gifted Education Models

Since the Marland Report (1972), which provided the first definition of giftedness to modern gifted theories, creativity has always been a key construct in giftedness. The Marland Report included creativity along with other abilities such as academic and intellectual talent, leadership, art and psychomotor abilities to define giftedness. However, creativity was recognized as part of high ability in earlier works. The work of Louis Terman showed that gifted children in his sample had higher creativity with a longitudinal study of 1,500 children with IQ scores above 140. Divergent thinking (DT) tasks were part of the first intelligence test developed by Binet and Simon (1905).

One of the theories that connect creativity to giftedness is the three-ring conception of giftedness. According to the three-ring model, there are three major components of giftedness: above average ability, creativity, and task commitment (Renzulli, 2012). Giftedness is viewed as the combination of these three constructs and high intelligence and task commitment without creativity fall short of a full expression of giftedness.

Another crucial contribution by Joseph Renzulli is the Enrichment Triad Model (1977). This curriculum model offers school-wide, accessible forms of enrichment. Type I enrichment involves general exploratory activities that expose students to a wide variety of interests. Type II enrichment consists of group training activities to develop critical, creative and learning skills. Teaching creative thinking and problem-solving skills would be a primary objective of Type II enrichment. Type III enrichment involves working on real problems in a self-selected area using their experiences on Type I and II enrichment activities. Engaging in Type III enrichment is a creative experience in itself that requires the application of creative thinking and problem skills acquired in Type II enrichment.

In his Triarchic Theory of Intelligence, Sternberg (2000) identified three types of intelligence: analytic, creative and practical. According to this theory, various patterns of giftedness can be demonstrated within each or as a combination of these three areas. Creativity is seen as one of the crucial components of intelligent human behavior. Although creative abilities may lead to novel ideas, the creative process requires analytic abilities to evaluate the implications of those innovative ideas. Likewise, the creative process needs to use practical ability to persuade others that those ideas are better than old ones. Generating ideas (creativity), assessing the quality of these ideas (analytic) and then implementing these ideas (practical) give rise to giftedness.

Later, Sternberg added wisdom referring to the consideration for the common benefit of all stakeholders. Without wisdom, the gifted individual may make use of their intelligence to achieve selfish goals. As the name implies, the WISC model of giftedness (Sternberg, 2009) necessitates having high levels of wisdom, intelligence, and creativity. Giftedness should be extended for the common good of the world. Wisdom involves the application of both intelligence and creativity for the greater good of all. WISC can be helpful in developing gifted abilities.

According to the Star model (Tannenbaum, 2003), giftedness can be identified through five elements: superior general intellect, distinctive special aptitudes, non-intellective requisites, environmental supports, and chance. The non-intellective requisite includes creativity, motivation, self-concept, and any other individual characteristics that are not part of cognition. Thus, creativity is not included in cognitive abilities but is listed as one of the psychological factors. Gifted potential transforms into two different types of giftedness: producers and performers. Producers generate thoughts or things whereas performers apply or complete these thoughts or things. Creativity and proficiency are necessary processes for both producers and performers.

Gagné (2009), proposed some natural abilities that contribute to giftedness in his Differentiated Model of Giftedness and Talent (DMGT) model. These natural abilities which consist of intellectual abilities, physical abilities, creativity skills and socio-affective abilities are the building blocks to acquire the skills and knowledge related to expertise in a particular domain. Children can demonstrate their capability in all of these domains at various degrees but a child is considered gifted when the level of expression becomes outstanding. Gagné made a distinction between giftedness and talent: Giftedness can be defined as natural ability in a particular domain, whereas talent in a specific domain starts with natural abilities which are then steered by interpersonal and environmental catalysts and chance. So, natural abilities require the appropriate environment to be transformed into talents.

The Munich Model of Giftedness (Heller et al., 2005) proposed seven relatively independent predictors which include intelligence, creativity, social competence, practical intelligence, artistic, musical and psychomotor skills. So, creativity is one of the individual potentials that can transform into excellence performances in various domains depending on non-cognitive and environmental factors.

Summing up, creativity is present in the major models of giftedness. Some of them view creativity as an ability that is necessary to manifest giftedness and some others see it as complimentary skills leading to the superior manifestation of giftedness.

Giftedness and mini-c

As the concept of giftedness evolved, the concept of creativity has undergone some changes as well. One of the newest concepts in levels of creativity can be the conceptualization of mini-c which is the beginning point of the continuum of creativity (from mini-c, little-c, Pro-c to Big-C). Big-C, Pro-C, and little-c creativity have product-oriented focus distinguishing levels of creative magnitude.

The most relevant creativity concept to giftedness might be mini-c which is recently proposed by [Beghetto and Kaufman \(2007\)](#). Generally, creativity used to be assessed through creative products. Mini-c creativity, which is rooted in Runco's "personal creativity", represents novel and meaningful interpretations of experiences that can later be turned into little-c or even Big-C creative outcomes. Expecting Big-C or little-c from a sixth-grade student can be unrealistic but intrapersonal judgment or insights can be transformed into interpersonal (little-c) or historical (Big-C) productions. A singular focus on creative products may lead to a failure to recognize creative potential. Apart from being important indicators of creative potential, the concept of mini-c is important for educators to cultivate the creative potential in their classrooms. The idea of mini-c provides a new direction for developing identification tools of creativity or creative giftedness as well.

Nurturing Creativity in Gifted Learners

A critical challenge in gifted education is whether and how youth giftedness and creativity turn into adult productive creativity and expertise. It is clear that there is no one right way to cultivate creativity in gifted learners. Here are some promising approaches to foster creativity among gifted students.

[Sternberg \(2017\)](#) proposed the Active Concerned Citizenship and Ethical Leadership (ACCEL) Model which underlines the need for ethical leadership to achieve common good for all. He noted that gifted students are especially vulnerable to lack of foresight such as unrealistic optimism, egocentrism, and unethical engagement because they may believe that they are safe from these fallacies. Therefore, the ACCEL model of giftedness advocates for the development of analytical, creative, practical, wisdom-based and ethical skills among gifted students.

Our societies face complex social issues that need solutions. Instead of being separated from society, gifted students should be educated as expert real-world problem solvers. They need to be taught critical and creative thinking, common sense and wisdom. [Sternberg \(2017\)](#) argued that we should concentrate on preparing gifted students to become transformative and ethical leaders who have analytic, creative, practical, wisdom-based, and ethical skills rather than focusing on traditional IQ-based approaches. In this model, taking responsibility in a family is an important leadership role. So, the quality of leadership matters rather than the level of leadership. Sternberg emphasized the importance of ethical skills that focus on decisions made by focusing on the right thing is to do, not just the benefits of shareholders and consumers.

[Beghetto's \(2017\)](#) legacy projects seem to be in line with the ACCEL model. Legacy projects are student-directed, creative efforts to make positive change by focusing on complex challenges in students' environments. These projects require gifted students to work on real-world problems and to cooperate with others to find solutions. While tackling ill-defined problems, they should think and act creatively. Therefore, legacy projects can provide students with first-hand experiences of developing their creativity and problem-solving skills. Beghetto uses these following questions to design a legacy project addressing problem identification, developing a rationale for the importance of these problems, taking actions to do something about such problems and planning for ways to sustain and maintain the work:

- What is the problem?
- Why does it matter?
- What are we going to do about it?
- What lasting legacy will our work leave as a result of addressing this problem?

The Future Problem Solving Program (FPSP) was developed by E. Paul Torrance to teach students to use creative problem-solving skills on complex challenges of the future. FPSP helps gifted students increase their awareness of critical issues and adapt to a changing world and turn the challenges into creative solutions. Students apply creative problem-solving skills when solving a real-life problem in each of the FPSP components. For instance, global issues problem solving requires students to employ creative problem-solving processes to respond to some future global scenarios. In community problem-solving, students examine their societies and develop a project to find solutions to community issues and then implement their plans. Scenario writing asks students to write a futuristic short story based on their future projection of given issues. In scenario performance, students create and perform a 5-min oral story on one of the given topics. Action-based problem solving is developed to master creative problem-solving steps in classrooms.

Conclusion

Most contemporary theories of giftedness view creativity as a core component. Creativity is more important today for gifted education than ever before because the future is unpredictable and change is occurring faster than ever. It is important that educators pay recognize students with high creative potential. Gifted students should be given opportunities to cultivate and enhance their creative

thinking skills as part of their differentiation and enrichment activities. Educators should develop programs fostering creative thinking skills.

Good Work in Pre-collegiate Education

Weihua Niu^a and Qianlin Liang^b, ^aDepartment of Psychology, Pace University, New York, NY, United States; and ^b Pace University, New York, NY, United States

© 2020 Elsevier Inc. All rights reserved.

The world needs creative people who generate novel ideas and think creatively to cope with the ever-changing world. Society also needs more good workers who get things done, and done well despite challenges and difficulties, not only to satisfy their own needs but also for the benefit for the society in the long run.

Creativity, as agreed among most creativity scholars, carries two core elements: originality and quality. The second element, quality, has many variations, such as usefulness, appropriateness, effectiveness, or aesthetic appeal, depend on the domain in focus (Runco and Jaeger, 2012). Creative thinking process often involves some-levels of rule-breaking or deviation from the standard. There is no ethical standard necessarily binding on creative individuals, nor creative acts and products. In other words, creativity can be used in both constructive and destructive ways, depending on who operates it, either in accordance or defiance ethnic principals, to achieve either ethical or evil goals.

A new body of literature called Good Work examines the positive or ethical aspect of creativity. This emerged in the late 1990s. Most if not all scholarly publications in this area have been produced by scholars associated with the Good Work Project, led by three psychologists: Howard Gardner, Mihaly Csikszentmihalyi, and William Damon. The Good Work Project was a large-scale effort to identify individuals and institutions in various domains that exemplify good work – work that is excellent in quality, socially responsible, and meaningful to its practitioners. An ultimate goal of the Good Work Project is to determine how best to increase the incidence of good work in our society (The GoodWork Project Team, 2008).

The initial construct was called “humane creativity,” or socially responsible creativity, the kind of creativity that not only satisfies personal or an institutional interest but is done for the benefit of a broader society for a long run (Gardner, 2010). The concept was gradually evolved to good work to reflect the missions of the project better; that is, to understand what and how leading professionals or exemplifying workers do to make a difference in their jobs and how to increase the incidence of good work in our society (The GoodWork Project Team, 2008). Whereas creativity does not require an ethical standard binding on individuals, professionals (the workers) usually have a social contract binding them to a set of standard that benefits society. The word for creativity was eventually replaced by “excellence” to stress the technical aspect of the “work,” while two other Es were added: “ethics” and “engagement” to emphasize both social and personal meanings of the work. The definition for good work, therefore, requires three aspects: (1) technically excellent, (2) personally meaningful or engaging, and (3) being carried out ethically. The concept was best illustrated using three intertwined spiral chains, similar to the DNA helix, which they call the ENA.

The objectives and the score of the good work projects focus on two major themes, one theoretical and the other more applied. The first theme is to investigate the meaning of good work in different professions (also called the domains) and how successful individuals and institutions in different domains carry out good work in the face of intense, and often conflicting pressure. Through this line of research, prototypes of good work carried out by good workers may be established. The second theme is to develop the Good Work Toolkits based on the outcome from the first theme and, in working with individuals and agencies who are in charge of training young professions, to apply these toolkits to train future good workers in different domains (Gardner et al., 1997, 2001).

Since the late 1990s, a vast amount of empirical studies have been completed using the Good Work Framework developed over the years. The primary approach of the framework is to use semi-structured interviews with outstanding professionals in different domains, averaging 2 h in length, to create a rich database that can be mined in many ways both for the time of the study and for other researchers to explore in the future. Each research project may have its own objectives, but the framework provides a foundation for researchers who conduct the interview studies in various stages including drafting interview questions, choosing a sample, conducting the interview, and finally coding and analyzing the data. For example, under the framework, interview questions are designed to cover nine major topics ranging from beliefs and values, work process on the personal level, positive and negative pressure at work, formative background, perspectives on work, community and family relationships, and ethical standards. Interviewees are typically informants who are experts or a representative sample of the examined domain. There are recommendations on how to conduct the interviews.

After the interview, the audio materials are transcribed into text and reviewed by the interviewees before being converted into standard format of transcripts following a general coded reading guide. This conversion procedure is regarded as the first level of coding to ensure the most important information is captured and placed under the most appropriate heading. After the first step coding, the converted transcript is further coded based on a coding manual, which contains 3–5 pages of information arrayed on 10–20 coding sheets. The coding manual contains detailed instructions on how to code the transcript as well as precise definitions and examples of their pre-determined 11 codes (Gardner et al., 1997, 2001). Coders were trained through ongoing discussion and testing to refine and clarify codes. Multiple round of training ensure a satisfactory and stable inter-rater reliability.

This standard procedure for all interview studies produced by the Good Work Project allows researchers to identify variables clearly and to address different questions at different stages of the research. Some recorded texts are descriptive to be used as testimonies in the report; others allow for further analysis of the data via descriptive and inferential statistics. This procedure can effectively reduce the amount of descriptive information so that all researchers may explore the rich data now and in the future to examine relationships among different variables. For example, in a study to investigate how certain individuals succeed in devising

strategies that are both creative and socially responsible, researchers followed the framework to code the materials, which allow future researchers to reanalyze the data to examine other questions.

Additionally, the Good Work Project supplements the interviews with other sources of information such as examining their creative works, talking about the work with informants, as well as participating in a follow-up survey, asking them to rank order 30 values held by them and by other professionals. Examples of the 30 values are broad interests, challenge, courage or risk-taking, faith, fame or success, self-examination, social concerns, and vision.

The empirical data accumulated in over two decades are enormous and open to many possibilities. For example, in its first ten years, the Good Work Project had interviewed over 1200 professionals across nine different domains, including genetics, theater, journalism, law, medicine, pre-collegiate education, tertiary education, philanthropy, and business (Gardner, 2010). More professionals were surveyed and interviewed in the next decade, including those who are in digital media, the arts, sports, interdisciplinary work, and other domains. Toolkits have been developed and utilized in various domains. Comprehensive reports and a systematic collection of books and research papers are available on the Good Work Project website, separated by the domain of focus (available via goodworkproject.org).

It is neither possible nor necessary to provide an overview of the vast amount of work produced under the Good Work project. Instead, this entry to the Encyclopedia examines one domain, pre-collegiate education. This provides a glimpse on how good work is empirically examined and what practical implications can be derived to help readers to appreciate the work and explore this line of research.

When examining the good work in the domain of pre-collegiate education, we focus on introducing three areas of research: (1) what are some challenges and ethical dilemmas educators and students face when thriving for success, (2) what is the meaning of good education and how educators carry out good work when external conditions work against them, and (3) the Good work toolkit in pre-collegiate education and how to use it to train future good students and good teachers.

Like in any other domains, individuals and institutions in pre-collegiate education face their challenges to meet professional and ethical standards. This becomes especially difficult when higher education has become more and more commercialized. The increasing market driven efforts in higher education has a ripple effect to pre-collegial education that challenges both educators and students to stay focus on their educational goals and personal passions, rather than giving in for a short-term goal and simply doing compromised work. Several studies were conducted to address this pressing issue.

Using the Good Work Framework, Redding (2010) examined the state of for-profit college counseling in the United States. She interviewed 13 stakeholders of the field, who play critical roles in either college admission process or in regulating the profession. These interviewees include leaders in professional organizations, partners in certificate programs, deans of college admissions, independent counselors, and scholars. The results are quite alarming. Although professional organizations encourage ethical, engaged, and excellent work of college counseling, there is a lack of gatekeepers' level of regulation to the field, especially for those who do not join these organizations. There is no required core knowledge for individuals entering the field of counseling, nor a strict requirement of professional membership to reinforce and sanction ethical guidelines to all professionals. The lack of field regulation leaves many unqualified consultants doing compromised work, and some even engage in dishonesty and manipulation, which leads to increased confusion, heightened frenzy, and continued inequity. Moreover, the consultants reshaped the process and expectations from the admission office, "enhancing the sense that there is a secret information" in college application.

Getting into good universities and exam culture creates challenges and dilemmas to educators not just in the United States but globally. Followed the Good Work Framework, Chia (2011) surveyed 20 Singaporean teachers and interviewed 10 of them to examine the impact of high stake exams on high school education. The result indicates that, although all interviewees believed that tests scores and student academic achievement are two separate things, they have to struggle to deal with the conflicts between helping students to excel in exams and providing good education. They also endorse that good education means to promote students' characters such as the spirit of curiosity, the quest for the universal human good, and healthy relationships that can last a long time and are for the benefit of the society. Chia asserted that schools, society, and national leaders should all play important roles in change the dilemmas and conflicts. A top-down initiative from the government is recommended to change the reality and to build "thinking schools" or eventually "a Learning Nation." In the end, Chia proposes a new model, adding enduring as a forth E, aside from excellent, engaging and ethncial, in promoting good work in pre-collegiate education in Singapore.

Increasing pressure of exam culture and the pressure of getting into top universities for future economic gains also affect student's good work in schools. Boddy (2015) surveyed 24 seventeen years old boys who are from a private high school in London and conducted a whole group discussion. The result indicates the exam culture left students little room for exploring their life's purposes and passions. Instead, students focus only on academics and allocate most if not all their resources into many extracurricular activities that could potentially help them to enter elite universities.

Even for those who are already admitted into elite universities, economic gain and career security may still drive students away from doing a good work. Locker et al. (2014) surveyed 40 Harvard seniors and interviewed seven of them. The result indicates the existence of "funnel effect" – an effect that more and more students chose to select a few careers with a higher economic gain. More specifically, the results showed that many humanity-major students chose to pursue a career with a higher payment such as finance and consulting; rather than related fields such as history and language that interest them at the first place.

The best approach to understand the good work in any profession is to get a perspective from outstanding professionals who are more knowledgeable about the good work in the profession. Fischman (2006) interviewed 16 informants – leading experts who are

working in the field of education. The result indicated that the informants rarely agree on some fundamental questions such as the purposes of education, the definition of good teaching, motivation to carry out good teaching under pressure and challenges, as well as methods used to improve the quality of education. Nevertheless, three areas of education are identified as important factors to assess good education, which are, structure changes in schools, quality of instructional practice, and student engagement and teacher-student relationship. These three factors are agreed among major stakeholders of education, such as administrators, educators, superintendents, parents, government, and school reform experts.

Applying the knowledge learned from their research to practice, the GW Project developed a series of toolkits to engage individuals and groups in conversation and reflection about good work. The first toolkit was published in 2010, which contains a guidebook filled with narratives and dilemmas faced by workers, a book of 50 narratives selected from 1200 individuals interviews over the 10 years, and a set of cards with varying values on each intended to be sorted into most to least important. Since the introduction of the toolkit, it has been used in different settings including high school and college classrooms across the globe.

The toolkit was also modified to adapt to younger audience including elementary school students to emphasize the message that carrying out responsible, high quality, and honest work is important at any age, and the younger students begin to appreciate ethics, excellence, and engagement as workers and citizens, the more powerful their understanding will be. All the narratives and activities were revised to adapt word choice and ideas suitable for a younger student. The toolkit was further developed as a set of lesson plans to be used in both upper grade elementary school students and middle school students.

Sample toolkits and lesson plans are available on their website at <http://thegoodproject.org/toolkits-curricula/the-goodwork-toolkit/>. Through developing these toolkits and lesson plans, the GW project formed collaboration with schools both within the United States and around the world (Fischman, 2010). The extent to which the toolkit can be generated in the global context is still in investigation. Nevertheless, toolkits have a lot of potentials in the field of pro-collegiate education, which primary objectives to train future good workers who can contribute positively to our society as well as fulfilling their personal goals.

In this chapter, we introduced the background of good work, its origins, and framework for conducting research in this area. We also provide a brief summary to research on good work in the domain of pre-collegiate education. So how to evaluate the 20-year research in good work and what lessons do we learn from this body of research?

First, how do insiders view the accomplishment of the GW Project? Have they achieved the goals they have set up initially and what kind of work left for the future?

The GW Project generated plenty of interests both within the academic circle, including the field of creativity research and education, and public and applied sectors such as schools, companies, and policy makers. This can be seen from the reception of the work from audiences at professional conferences, the expansion of its theory and framework, as well as increasing collaborations from various individuals, groups and institutions to attempt work together to execute good work, teach the topic, and apply the theories in different educational realms. Most importantly, the questions the project asked and the ongoing dialogue it nourished have a far-reaching effect for both academics and the general public (Gardner, 2010).

However, despite the enthusiasm scholars and publics have demonstrated when knowing about the work produced by the Good Work Project, there are still lack of recognition from both the field of psychology and the general public (Csikszentmihalyi, 2010). Most research papers are yet published in peer-reviewed "A Class" journals. Publics and applied sectors are also struggled to embrace the findings of the project. For example, several projects were developed to get perspectives from both educators and students about what the purposes of education are and what actually students got. The results showed a misalignment between the educators and the students on these questions. Whereas educators endorse a notion that an important objective of education is to provide students with cognitive tools like critical thinking and analytical skills, students emphasize more on learning how to live a good life, a goal that educators often deemed as hedonistic. When such results were shared with stakeholders in a hope to diminish the gap between educators and students, there lack of acceptance to address this issue from the school administrators.

For those who are interested in joining the dialogue of good work and become a researcher in studying good work, we would like to make two recommendations based on what we've learned from the 20 years in good work.

First, the field of good work is still a new and growing research area. It addresses important academic and social questions that can have a long-lasting impact on the field of psychology and many other fields. The specific research questions GW scholars have asked are profound and often challenge the core of a discipline. For example, in the domain of education, researchers ask questions such as the definition of good education and the ways to execute a good education in the face of intensive conflicts and pressures. All these questions are hard to study using conventional methodologies. To respond to this, the GW Project develops a framework to examine these questions systematically. The results often lead to many new questions than answers. The project has generated a rich database to allow future researchers to reanalyze and address further questions. At this stage, more research is needed to further examine the GW theory as well as its framework. More practitioners are also needed to apply the knowledge gained from previous studies to change any unfavorable reality of our society, which will help train future good workers.

Second, as mentioned at the beginning of this article, most if not all studies are produced by scholars associated with the three psychologists. A PsycINFO search with a keyword of "Good work" only yielded 19 entries and most are unrelated with the GW work introduced in this article. This feature suggests that the field of good work is very much self-sustained. The usage of qualitative methods and the adoption of a comprehensive framework make replications harder. Nevertheless, for the healthy growth of field, more independent research is needed to verify findings from the GW project.

However, despite the enthusiasm scholars and publics have demonstrated when knowing about the work produced by the Good Work Project, there are still lack of recognition from both the field of psychology and the general public (Csikszentmihalyi, 2010). Most research papers are yet published in peer-reviewed "A Class" journals. Publics and applied sectors are also struggled to embrace

the findings of the project. For example, several projects were developed to get perspectives from both educators and students about what the purposes of education are and what actually students got. The results showed a misalignment between the educators and the students on these questions. Whereas educators endorse a notion that an important objective of education is to provide students with cognitive tools like critical thinking and analytical skills, students emphasize more on learning how to live a good life, a goal that educators often deemed as hedonistic. When such results were shared with stakeholders in a hope to diminish the gap between educators and students, there lack of acceptance to address this issue from the school administrators.

Introduction

Creativity and innovation are necessities for development and survival in a modern world where problems and challenges such as war, disease, and global warming are complex and come with unpredictable consequences. In many aspects of life, from economics to politics, and from education to the sciences, governments need to set up clear and explicit strategies that consider creativity as a corner stone. If they do not place creativity, a prerequisite for innovation, as their highest priority, policymakers cannot expect workers or employees to behave creatively and accept creative change. Governments that believe creativity is a valuable human resource will invest and support creativity in their plans and initiatives.

Geographic size or population of a county is no longer a salient feature; on the contrary, national assessments feature economic, technological, and educational indicators. Creative and talented individuals create soft power for small countries that design their economy and address intractable environmental problems.

For example, Singapore, a small country in Asia that has few natural resources, is competing with the richest countries. The Global Innovation Index ranking (GII; 2018) placed Singapore in fifth place, outperforming many rich countries such as the United States, Germany, France, and Japan. Moreover, Singapore is ranked first in the Innovation Input sub-index of the 2018 GII report. How could a small country such as Singapore compete with much bigger economies? One of the answers can be found in the Research Innovation Enterprise 2020 Plan in which the Singaporean government assigned \$19 billion of its budget to support research, innovation, and enterprise. According to the National Research Foundation Plan, four categories of researchers were supported: (a) early career researchers, (b) mid-career researchers who are expected to become scientific leaders in future, (c) multi-disciplinary teams conducting cutting-edge research, and (d) outstanding Singaporean researchers who have established themselves abroad with the opportunity to relocate their research back to Singapore. Other examples of governments supporting creativity and innovation are the Dubai government through their Mohammed Bin Rashid Center for Government Innovation, the Canadian government through its Innovation, Science and Economic Development program, and the United Kingdom Research and Innovation Agency. These, and other examples of institutes that invest in creativity and innovation help explain why some countries are taking the lead in terms of economic status. Moreover, these examples demonstrate that supporting creativity should be a systematic and a planned effort by the highest authorities within the government.

This entry synthesizes and summarizes the current governmental efforts to support creativity. The following topics will be addressed: (a) discussing individual and organizational creativity, (b) comparing creativity in the public with private sector, (c) supporting creativity in k-12 education, (d), discussing environmental factors that encourage creativity in the government, and (e) supporting creativity research. Building on the previous sections, the final part of this entry concludes by offering a suggested definition for the term "creative government." It also provides some ideas for governments that aim to invest in creativity and innovation.

Individual and Organizational Creativity

The majority of creativity research during the last six decades focused on the individual level rather than the broader organizational level. The focus was on the characteristics distinguishing creative individuals, creative processes in which novel and useful ideas were being originated, transforming creative ideas into tangible products, and finding the ideal climate that fosters and encourages creativity and creative behavior. The past two decades witnessed an increase in studying creativity and innovation in organizations as

evidenced by books, book chapters, and peer reviewed articles. Moreover, policymakers have emphasized the value of creativity for social advancement and economic growth as reflected in their speeches, national plans, strategies, and reports (Runco, 2014; Runco and Abdulla, 2014).

Defining *creative government* is not easy at all. Perhaps some might question if such a concept exists. However, before defining creative government, it is important to define creativity in organizations as it is related to the context/nature of work in governments. Many creativity researchers are familiar with Rhodes 4P's (that is Person, Process, Press, and Product) in which an individual is the unit of interest and starting point for assessment. Still, there is a good reason to believe that what characterizes creative individuals applies also to organizational creativity. Amabile and Pratt (2016), for example, presented a dynamic componential model of creativity and innovation in organizations in which both individual and organizational creativity dynamically interact with each other. According to Amabile and Pratt (2016), creativity in organizations requires: (a) skills in innovation management, which corresponds with creativity-relevant processes in individual creativity; (b) motivation to innovate, which corresponds with intrinsic motivation in individual creativity, and (c) resources in the task domain, which corresponds with the third component of the individual creativity, skills in the task domain (see Fig. 1).

Some definitions of organizational creativity also showed that individual and organizational creativity are interrelated; both require originality and usefulness. For instance, Woodman et al. (1993) defined organizational creativity as 'The creation of a valuable, useful new product, service, idea, procedure, or process by individuals working together in a complex social context' (p. 293). Krueger and van Genugten (2017) suggested that "Work-related creativity is defined as an employees' ability to come up with new and useful solutions to improve work-related practices" (p. 826).

De Vries et al. (2014) conducted a systematic review on innovation in the public sector analyzing 158 articles published between 1990 and 2014. De Vries et al. (2014) defined innovation in the public sector as, "The introduction of new elements into a public service – in the form of new knowledge, a new organization, and/or new management or processual skills, which represents discontinuity with the past" (p. 5).

Figure 1 The dynamic componential model of creativity and innovation in organizations (Amabile and Pratt, 2016, p. 162).

Although, individual and organizational creativity operate in different ways and employ different dynamics, governments need to consider both individual and organizational creativity. More about the former will be discussed in 'supporting creativity in K-12 education' section. The next section explores whether creativity in the public sector (i.e., government) differs from creativity in the private sector.

Creativity in the Public and Private Sectors

Research investigating creativity and innovation in the public sector have recently attracted more attention (e.g., Rangarajan, 2008; De Vries et al., 2014) which allows researchers to compare creativity and innovation in non-profit and for-profit organizations. In the non-profit public sector, services such as education, healthcare, and law enforcement originate from public governmental sources; whereas, for-profit private organizations such as family owned business, medical partnership, and corporations such as Apple originate from private sources formed with the goal to make a profit. Empirical works indicate that there are notable differences between the public and private sectors such as the space and flexibility these two sectors allow for creativity and creative thinking, the process of decision making (i.e., centralized vs. decentralized), environmental and psychical reinforcements, expectations from employees to behave creatively, and sources of motivation (i.e., intrinsic vs. extrinsic) (Amabile, 1997; Damanpour, 1991).

Furthermore, literature on creativity and innovation in organizations point out that: (a) the public and private sectors operate under two different systems/dynamics, (b) there are different types of innovation in organization (e.g., radical vs. incremental), (c) the levels of innovation allowed is different in the public than private sector, and (d) the outcomes sought by each sector also differ based on each sector's nature and objectives. Damanpour (1991), who conducted a meta-analytic review on organizational innovation, reported that the relationship between non-profit and profit organizations significantly differed in: (a) functional differentiation, defined as 'the extent to which an organization is divided into different units; ' (b) formalization, which 'refers to following rules in conducting organizational activities; ' and (c) centralization, defined as 'locus of authority and decision making and the extent to which decision making autonomy is dispersed or concentrated in an organization' (p. 589).

Rangarajan (2008) concluded that the most frequent pairs of creativity in government are proactive creativity and forward incrementation creativity. According to Unsworth (2001), 'Proactive creativity occurs when individuals, driven by internal motivators, actively search for problems to solve' (p. 8), Sternberg et al. (2001) stated that forward incrementation creativity 'occurs when a piece of work moves a field forward in the direction the field already is going to a point to which people are ready to go' (p. 85). Rangarajan (2008) concluded that in most cases, creativity in the government was incremental and was perceived as a reaction to a problem rather than an opportunity.

These, and other studies support the idea that types of creativity in the public sector differs from creativity in the private sector. But what makes creativity and innovation in the public sector different than creativity in private sector? And which sector is more encouraging for creativity and innovative work behavior?

Tasaduq and Azim (2012) compared creativity levels between public school and private school children in India. They concluded that private school students scored much higher on a non-verbal creativity test than their counterparts in the public school. Tasaduq and Azim (2012) reported that environmental factors such as lack of sufficient opportunities, lack of encouragement, and lack of proper facilities characterized public schools. Rangarajan (2008) identified other factors characterizing public schools such as higher levels of scrutiny and oversight, lack of a competitive environment, cautionary culture, strict procedural regularity, preference for the status quo, legal restriction, and the short time horizon of politicians and top administrators.

In a study conducted with a different age group and context, Bysted and Jespersen (2013) compared public and private sectors in Denmark, Norway, and Sweden in terms of managerial mechanisms (i.e., financial, decentralization, and participative). More specifically, they looked at eight variables (salary bonuses, recognition, innovation trust, safety, autonomy, competence, idea generation, and idea realization). The differences were: (a) employees in the public sector were most likely to behave creatively when they were financially motivated (i.e., get bonuses), (b) decentralization mechanisms had a positive impact on workers' innovative behavior, (c) creating a safe environment for employees increased innovative behavior, and (d) employees in the public sector perceived innovative behavior to be something extra that needed to be rewarded while employees in the private sector thought of innovative work as an opportunity for their career development.

Finally, Fidan and Ozturk (2015) studied the relationship between intrinsic motivation and the climate for creativity for both public and private schoolteachers in Turkey. The results indicated that the private school teachers were more intrinsically motivated to be creative and scored higher on a creativity scale.

In sum, these findings suggest that the private sector offers a more encouraging environment for creativity and innovation than the public sector. The public sector run by government needs to find ways to build a culture that boosts creative and innovative behavior. Moreover, governments need to construct a system that encourages flexible thinking, autonomy, and risk taking. K-12 education is a good place to start.

Supporting Creativity in K-12 Education

In the past few decades, educators became more concerned whether educational systems are doing a good job preparing students for the unpredictable future. It is highly important that K-12 education provide students with the most advanced knowledge that keeps

them up-to-date, but the advancement of humanity was never made by those who possess/acquire knowledge; it is based on those who use the current knowledge to create a new one. This section is divided into two sections. The first discusses whether the educational system in K-12 education value and appreciate creativity or not, and the second shed light on the issue of investment on education.

Valuing and Appreciating Creative Thinking

There are so many ways in which governments, as represented by ministries of education can do to nurture creativity from childhood through adulthood. Perhaps the most important, and a prerequisite of any other effort to support creativity, is to value and appreciate creativity.

Torrance's well-known work on the fourth grade slump was one of the earliest attempts to shed light on the negative effect of educational systems on creative thinking. Torrance longitudinal study showed that there is a significant slump in fluency, flexibility, originality, and elaboration scores (Torrance, 1968). Torrance was explicit about the significance of valuing creative thinking:

It is my firm belief that every educator from kindergarten through the graduate school should always be on the alert to notice new ideas proposed by children and young people, and to encourage such individuals to continue the development of their creative talents. Every educator should consider this as important, or more important, than teaching information.'

Torrance (1995, p. 25)

Sadly, this is still not the case. Educational systems emphasize teaching information more than teaching cognitive skills including creativity. Some researchers found that educational systems slowly kill creative thinking. Kim (2011) found that creative thinking, as measured by the Torrance Test of Creative Thinking (TTCT), decreased in the sixth grade.

A recent investigation concluded that students display more creativity outside of school than inside school; something which authors called 'creativity gap' (Runco et al., 2017) In an international survey 1150 respondents consisted of teachers, students, and policymakers from 149 countries around the world, were asked the following questions: 'how well is the overall educational system in your country performing in teaching students the following: math, reading, science, technology and computer skills, teamwork, arts, physical well-being, environment responsibility, critical thinking, entrepreneurship and business, and innovation and creativity?' 75% of respondents indicated that their respective countries are doing only fair/poor job teaching innovation and creativity. Results per region showed that only 9% of East Asian countries are doing excellent/good job teaching innovation and creativity. The highest percentage was in US/Canada/Australia/New Zealand region; 49% of respondents think that their countries are doing excellent/good in teaching innovation and creativity. In sum, it seems that creativity is not valued as much as academic areas such as math, writing, and science. Thus, it is not surprising that many governments around the world are not well investing in education.

Investments in Education

A government that values creativity will invest in students creative potential. Potential refers to unrealized ability that can be developed in future. There is no guarantee that creative potential will result in future creative achievement. However, research indicated that creative potential, as assessed by divergent thinking tests can predict future achievement more than many cognitive abilities including IQ (Runco et al., 2010).

Investment in creative potential can take different forms such as: (a) infusing creative thinking skills in curriculums; (b) teaching strategies that aim to enhance creative thinking; (c) exposing students to different learning experience; (d) encouraging independence through different means such as school assignments and projects; (e) building a safe environment where students are allowed to make mistakes without thinking of being criticized or punished; (f) offering equipment and facilities that allow students to practice their creativity; (g) preparing teachers to deal with creative students, identify their creative potential and support it (see Education and Creativity).

A significant area of investment in education lies in establishing and supporting gifted programs. Although creativity can be observed in all students, special attention should be paid to girls or boys who show early signs of exceptional behavior. As Brody and Stanley (2005) stated: "Some individuals do have special talents, and recognizing and nurturing these talents is crucial not only for the individual but also for the future of society, as these individuals have the potential to be our future problem solvers" (p. 26). In fact, the notion of gifted education is based on identifying those students who show early sign of exceptionality (i.e., potential) in order to provide them with unique educational experiences that could potentially result in future creative achievements.

Data from the GII supported the abovementioned argument that investment in education is crucial and directly affects countries' creative outcomes. The GII 2018 report showed that governments in the top ranked countries invested more in education compared with lower ranked governments. For example, governments in Switzerland (#1), United Kingdom (#4), Finland (#7), and Denmark's (#8) expenditure on education ranged from 5.1% to 7.6%, as a percentage of their GDP while governments in countries like Philippines (#73), Pakistan (#109), Bangladesh (#116), and Guinea (#119) expenditure on education ranged between 2.4% and 2.8%.

This in turn influenced the pupil-teacher ratio. The more the government invested in education, the lower the pupil-teacher ratio. For instance, the pupil-teacher ratio in Switzerland, Denmark, and Finland was 9.3, 11.3, and 13.2 respectively, compared with the pupil-teacher ratio in Philippines, Guinea, and Bangladesh of 26.2, 33.1, and 36.2 respectively. To conclude, K-12 education needs to value and support creativity. Both are highly related; when you value something, you will invest on it.

Creative Environment

This discussion on creativity and government would be incomplete without addressing environmental factors that inhibit or facilitate creativity. The main question here is how governments can create an optimal environment in which individuals feel safe, supported, and motivated to behave creatively. Previous literature suggests that physical, contextual, and motivational factors all play an important role for both individual and organizational creativity. [Amabile \(1997\)](#) suggested six factors that encourage creativity: organizational encouragement, supervisory encouragement, work group support, sufficient resources, challenging work, and freedom; and two factors inhibiting creativity: organizational impediments, and workload pressure ([Amabile and Pratt, 2016](#)).

There are different ways in which organizations can cultivate employee creativity, many of which apply to government organizations. Among these are specifying clear organizational goals, valuing innovation, supporting risk-taking, rewarding and recognizing creative work, and evaluating employees' fairly. Moreover, public sector organizations can support creativity by offering sufficient resources and materials, sufficient time, access to information, training opportunities, and funding creative projects. To summarize, government that put creativity and innovation as a top priority should consider environmental factors including:

- Finding different ways to motivate workers
- Valuing creativity and creative thinking
- Offering a degree of freedom and autonomy for employees
- Providing sufficient materials, both physical and intellectual
- Rewarding and recognizing creative ideas and projects
- Offering challenging works for employees
- Considering the physical environment that encourages creativity
- Treating its employees fairly with clear criteria
- Providing advanced training for employees
- Encouraging diverse ideas and communication between employees in different departments

Supporting Creativity Research

The number of research grants allocated for creativity research is indicative of the degree to which governments value and support creativity. This investment can take different forms including supporting distinguished initiatives and programs that aim to enhance education, improve creativity and innovation, develop valid and reliable measures to assess creativity at the personal as well as organizational level, and fund research that aims to better understand and develop creativity and creative thinking. The latter issue is very important because good practices should be based on solid theoretical arguments. Supporting creativity research can save time and effort by suggesting what works and doesn't work in programs, strategies, assessments, and environments.

Are governments supporting creativity research, and to what extent are practices in the public sector research-based? This issue was empirically investigated recently through a number of studies, which examined award grants assigned for creativity research as compared with other topics such as intelligence, motivation, memory, and 21st century skills ([Abdulla and Runco, 2018](#); [Runco and Abdulla, 2014](#); [Runco et al., 2015](#)). The first of this series of studies examined the public records in two US government agencies: The National Science Foundation (NSF) and the Department of Education (DOE). The DOE offers two databases: Grant Award database and Institute of Education Sciences (IES) database. [Runco and Abdulla \(2014\)](#) compared the percentage as well the amount of fund granted for creativity research by the IES with other areas of study. The result showed that creativity research was poorly supported in IES (2.1%).

The same search was done for the NSF awards database for the period from 1961 to 2013. The results from the NSF was better than DOE in terms of the number of awards allocated for creativity research ($n = 310$), with an increasing pattern of grants for creativity research from 1961 to 2013, except a notable slump in the 1990s. Still, the percentage of grants offered by the NSF for creativity research was only 1.3%.

In the second study, [Runco et al. \(2015\)](#) adopted a different method by examining the three main journals in creativity from 2004 to 2013: *Creativity Research Journal*, the *Journal of Creative Behavior*, and the *Psychology of Aesthetics, Creativity, and the Arts*. Among the 707 articles reviewed, 159 (22.5%) of the articles were supported by different funding agencies in more than 20 countries, as indicated by the researchers in their footnotes. The majority of funds were offered by the public sector (72%). Examining the geographical region for these funds showed that Asian countries provided the largest number of awards (32%), followed by the US (31.1%), Europe (22.4%), and other countries (14.5%). The NSF and The Ministry of Education in China offered the highest number of research grants for creativity research.

Finally, [Abdulla and Runco \(2018\)](#) compared the award grants offered by the NSF and IES for the 21st century 4C's skills: creativity, critical thinking, communication, and collaboration from 2005–16. The results showed that NSF funded projects involving collaboration and critical thinking, while IES funded communication and critical thinking projects. Both agencies gave minor support for projects involving creativity; a result that is consistent with previous studies.

When listening to policymakers and reading what is written in government official documents, one might feel that creativity is a priority for governments. However, this is not the case. The conclusion is that creativity is anecdotally supported when it comes to investments in creativity and creative individuals. As [Runco et al. \(2015\)](#) concluded, "Given the role of creativity in everything from health to education to innovation, the lack of support is a serious matter—and that is a serious understatement" (p. 109).

Conclusion

Creativity is an invaluable human resource that can enhance the quality of life. Although the field of creativity initially investigated individual creativity, in the last two decades both individual and team creativity have been about equally important.

The role of government in nurturing and supporting creativity begins with k-12 education. Another means in which government can invest in creativity is to support creativity research, make connections between theory and practice, create national plans and initiatives that support creativity at different levels of government, and setting up policies that support creativity. For example, the Canadian government, which established 'Creative Canada: Policy Framework' in 2017, Innovative UK 2015–19 Strategy, and the United Arab Emirates National Innovation Strategy.

This entry concludes with a suggested definition of a creative government: the creative government consists of an administration which values creativity, and thus, (a) invests in creative potential starting from k-12 education, (b) supports individuals transforming their creative ideas to tangible products (i.e., inventions) that are both novel and useful, (c) supplies funds for creativity research and practice, and (d) attracts talented individuals from other part of the world by offering an ideal environment for investments.

Group Creativity

Despite the persistent and often-cited stereotype of the ‘lone genius’, much creative work actually takes place in groups, teams, or other collaborative settings. This is especially true in organizations, where an increasing amount of work is organized in permanent or temporary teams (such as production teams, project teams, quality circles, etc.). It is also true in art (music, especially), science, sports, and any setting where something is to be gained by having multiple people work on a task together. Whereas creativity is usually defined as the generation of ideas that are both novel and useful, group creativity occurs when these creative ideas are the result of several people working together.

Properly organized, group work increases the amount of work that can be done, the amount of resources that can be drawn upon, and the efficiency with which it can be done. In terms of creativity, group work primarily means that creativity could benefit from the presence of a broader variety of knowledge, abilities, and traits. Furthermore, when group members are exposed to various inputs from other members, their creativity may be stimulated. Thus, group work can *stimulate* creativity to the extent that groups and their members manage to make use of (i.e., exchange and process) the information and perspectives available. In contrast, group creativity is *hindered* by factors that prevent groups from being creative either because information or ideas do not get shared or because they do not get processed and used within the group.

It should be noted that group creativity is not simply an aggregate of multiple individuals’ creative behavior. Groups are *multilevel entities*, meaning that their performance as well as the influences on that performance can exist on multiple levels. Thus, group creativity may depend on certain factors at the individual level (e.g., individual traits and abilities, individual contributions to the group) and the group level (e.g., group size and structure, characteristics of the group task, group processes and performance). It will also depend on factors at even higher levels of analysis, such as the organizational (e.g., organizational culture or mission, reward structures) or even the societal level (e.g., social norms, national culture, economic circumstances). Further, variables on higher levels will feed into lower-level variables (as well as vice versa): The individual creative behaviors of group members will be influenced by group-level variables such as task structure, group size, and group climate. For example, people working in a large group, where individual members’ contributions are not identifiable, may be tempted to free-ride on their fellow members’ efforts and contribute less than they could have. The group-level effect (i.e., the temptation to free ride as a consequence of identifiability) may exist for all members, but the strength of the effect may depend on individual differences (e.g., on an individual’s identification with the group). Thus, a thorough understanding of group creativity requires a multilevel perspective, recognizing that groups are more (or less) than the sum of their parts.

Building on this conceptualization, the remainder of this contribution will discuss two broad topics. First the evidence about creative performance in groups will be summarized, and then ways to make groups more creative will be discussed.

Creative Performance in Groups

Although creativity is not a linear process, many theorists and researchers adopt some sort of stage model of creativity, for example moving from problem definition to idea generation, via idea evaluation and selection, to idea implementation. In

the context of group creativity, research has primarily focused on idea generation, but research is increasingly beginning to study the later 'stages' of the creative process in groups.

Idea Generation

Many people will associate idea generation in groups with brainstorming sessions. The word brainstorming (using the brain to "storm" a problem) was coined by advertising executive Alex Osborn in his 1953 book *Applied imagination* (Osborn, 1953). He proposed that group idea generation would be stimulated when idea generation and idea evaluation are strictly separated: When judgment is deferred to a later moment, people do not fear evaluation and criticism and are more likely to share their wildest (and potentially most creative) ideas. Further, Osborn suggested that emphasis during idea generation should not be on idea quantity, because the more ideas that are generated, the more likely that some of them will be good. He converted these two principles, "deferment of judgment" and "quantity breeds quality," into four brainstorming rules: Quantity is wanted; freewheeling is welcomed; do not criticize ideas; and build on and combine previous ideas. Osborn also originally suggested that, when these four rules are followed, people would be more creative when they work in groups rather than alone, because group members may stimulate additional ideas from each other.

Brainstorming has since become one of the most used creative techniques. For example, the word "brainstorming" yields more than 75 million hits in a Google search (January 2019), of which almost 50,000 give advice on how to brainstorm more effectively (at least, they contain the phrase "effective brainstorming"). Moreover, the brainstorming technique has generated a considerable amount of research, allowing for a number of robust conclusions (see Stroebe et al., 2010, for an overview).

There is evidence that generating more ideas is associated with generating more good ideas, with "good ideas" defined as those that are both original and useful. However, sheer productivity (i.e., number of ideas, often also called idea fluency) usually is not related to the *average* quality of ideas. It is thus the case that generating more ideas implies generating more good ones, but also more bad ones (i.e., those relatively low on originality, usefulness or both). However, there is less clarity about the rule of not criticizing ideas. On the one hand, evidence suggests that a group climate in which ideas are shared openly without fear of criticism or ridicule – a psychologically safe team climate – is beneficial for creativity. On the other hand, some evidence suggests that (mild) conflict and dissent during idea generation can be beneficial as well. Conflict, however, only has these beneficial effects when it is constructive rather than personal and when the team climate is safe (see discussion below).

Most research has considered the question whether brainstorming in groups is more effective than brainstorming alone. When this question is asked to the general public, it appears that people across cultures (e.g., North America, Western Europe, Japan) share the belief that group brainstorming is more effective than individual brainstorming. However, when actually tested in research, this belief proved to be false: People actually generate more ideas and more good ideas when they brainstorm alone than when they brainstorm in groups. This is a robust finding and is usually referred to as the "productivity loss" of brainstorming groups.

Because this finding comes as a surprise to many, it is important to understand the methodology used in these studies. In particular, these studies compare the production of a (real, interacting) group of N people (say a five person group) with the production of so called "nominal groups" consisting of N people (e.g., five individuals) who work alone for the same amount of time ("equal person-hours comparisons"). After the brainstorming session, the production of these individuals is pooled, and duplicate ideas removed. The idea is that the performance of nominal groups should be a good estimate of group performance if interacting with others in a real, interacting group neither facilitates nor hinders individual idea generation. Research thus concluded that interacting in a group did not stimulate members' creativity, but rather inhibited it.

Research indicated that the effect may be partly due to lack of effort: People who work in groups may work less hard than individuals, who cannot "hide in the crowd." There is also some evidence that, despite the instruction not to criticize ideas, people are still somewhat reluctant to share all their ideas in a group (because of the fear of negative evaluation, often called "evaluation apprehension"), and that this is especially true for shy people. The most important cause, however, is *production blocking*. This refers to the fact that in groups usually only one person talks at the same time. This means that group members have to take turns to express their ideas and can only express them when no one is talking, which blocks their ability to produce ideas. Production blocking implies that group members often have to wait for their turn, and this has been shown to interfere with their ability to generate ideas.

Interestingly, if production blocking is an important cause of the productivity loss of brainstorming groups, this implies that the productivity loss should disappear if turn-taking is eliminated. This is exactly what was found when procedures were used that did not require turn-taking among group members, such as exchanging ideas through computers (electronic brainstorming; people can type simultaneously and read ideas of others on the screen) or through written notes (brainwriting; people pass on written notes to others but can write at the same time). In fact, there is evidence that sharing ideas is actually stimulating in electronic brainstorming and brainwriting groups, leading to ideas that people probably would not have generated.

Recent studies also looked at the degree to which group members followed the fourth brainstorming rule regarding combining and building on previous ideas (Kohn et al., 2011). Groups whose members actively followed the rule outperformed groups that didn't. Thus, cognitive stimulation in groups could happen either because hearing (or reading) somebody else's idea activates domain knowledge in long-term memory and hence leads to new ideas, or because group members actively try to build upon and extend the raw materials provided by other group members' ideas.

Another area of group work where cognitive stimulation (rather than productivity losses) is central, is *group improvisation* (e.g., in music or improvisational theatre; e.g., Sawyer, 2007). While a brainstorming session revolves around generating as many ideas as

possible, which is difficult to reconcile with group interaction (e.g., with the rule that only one person speaks at a particular time), other creative group tasks are more about collectively creating something by continually building upon each other's contributions. Thus, a jazz trio is (hopefully) not trying to produce as many new musical phrases as possible, but rather to use the group interaction to come to something new and valuable within a certain framework. However, probably due to difficulties in data collection and analysis in such naturalistic and spontaneous group interactions, most research on group creativity has focused on idea generation in brainstorming or similar tasks.

To summarize, the brainstorming literature suggests that brainstorming in the traditional way – sitting around a table and expressing ideas aloud – is not very effective. More successful methods include electronic brainstorming and brainwriting, exchanging ideas with others which can be stimulating. Stimulation may occur both as a consequence of exposure to others' ideas, or when people build on one another's ideas (e.g., during improvisation).

It should be noted that organizations may use group brainstorming sessions for other reasons than mere productivity (Sutton and Hargadon, 1996). For example, group brainstorming sessions are also thought to be useful to expose employees to a variety of ideas, possibly learning new things in the process, to stimulate transactive memory in the team or organization (i.e., 'knowing who knows what'), to act as a team-building intervention (e.g., because they can be a lot of fun to do and group members are able to contribute whatever they want), and to be a useful marketing tool towards (potential) clients. Thus, there may be other reasons to use brainstorming groups that are not necessarily invalidated by productivity losses.

Beyond Idea Generation

Although most research on group creativity has focused on idea generation, this is rarely the end of the creative process: additional steps include *recognizing* the most creative, valuable, or promising options, *refining* or *developing* ideas in order to satisfy different constraints, *selecting* ideas that actually deserve to be implemented, *promoting* ideas to stakeholders in order to gain the necessary resources, and of course *implementing* an idea into something that can actually be used or sold. All these activities can take place in a group setting; in fact, the closer one gets to implementation, the more likely coworkers, managers and possible clients are to get involved.

It has also been argued that these later stages of the creative process, such as idea evaluation and idea selection, are the ones where group work is more likely to be effective than individual work. Groups outperform individuals on so-called *intellective tasks*, where the search is not for ideas but for a demonstrably correct solution. In these *disjunctive group tasks*, only one member needs to find the correct answer for the whole group to succeed. Unless there is something about the group process that hinders members in searching for a solution (e.g., production blocking in idea generation) or sharing the solution with the group (e.g., evaluation apprehension, lack of safety), groups will generally outperform individuals on these tasks, simply because the probability of at least one of the group members finding the solution will be higher than the probability of a single member finding the solution. This may happen in so-called *insight problems*; there, the correct solution is usually recognized to be correct once it has been produced, and indeed groups do seem to outperform individuals on such tasks. However, creative problem solving is not an intellective, but a judgmental task; that is, there often is no clear 'correct' answer or solution. Consequently, the best idea is not automatically recognized when it is proposed.

Idea Selection

Research indicates that groups do not perform very well in selecting creative ideas (e.g., after a brainstorming session). Experiments on idea selection after group brainstorming consistently found that groups seriously underperform in terms of selecting their best or most creative ideas, sometimes even failing to perform above chance level: In several studies, the ideas that groups selected did not differ in quality from the average of their ideas. They seemed to prefer high feasibility over high originality. Thus, creative potential generated during brainstorming gets lost during idea selection. This is especially problematic in light of the fact that many interventions and techniques (such as brainstorming) seem to focus on getting groups to generate more ideas. Research on idea selection suggests that this can be a serious waste of time and money, since these ideas are likely to get lost in selection anyway.

Similar results have been found on the individual level, suggesting that this is not exclusively a group problem, but also reflects something about the way people respond to creative ideas. Because creative ideas are risky and unpredictable, they can cause uncertainty and can lead people to avoid them and to favor more familiar options that are known to be feasible. However, this may well be exacerbated by the group context: Considering that the selection of creative ideas is a judgmental task that typically is done through a 'majority wins' decision rule, and that biases present among individuals tend to become more influential under 'majority wins', the individual bias against originality may become even stronger in a group context. In contrast, as explained above, if idea selection were intellective (that is, a matter of finding a demonstrably 'best' option), group interaction should enhance performance (because the chance of at least one group member finding the best idea would be higher). The difficulty of selecting creative ideas, then, lies in the uncertain and unpredictable nature of highly original ideas, and this is also what makes it especially difficult for groups.

Idea Development

Raw ideas are rarely ready to be selected (or rejected) for implementation: Usually an idea will need to be refined, improved, elaborated, and/or adapted to the constraints of reality before selection and implementation can take place. Like idea generation, idea

development, or the process of refining and improving ideas, can be done by individuals, but is often likely to happen collaboratively. Idea development processes do seem to contribute to groups' idea generation and selection performance, suggesting that idea development is not necessarily an intermediate stage on the road towards selection, but can in itself lead to cognitive stimulation effects (or even to redefinition of the problem), and hence to new ideas (e.g., [McMahon et al., 2016](#)) (See Problem Finding).

An additional possibility is that idea development opens the door for better idea selection, because it allows one to improve an idea in order to have it satisfy multiple criteria (e.g., high originality *and* high feasibility). Thus, if an idea has appeal because of its high originality but seems unfeasible, rather than rejecting it out of hand, the idea could be refined or revised to make it more practical or easier to implement, while retaining the novel aspects of the idea. Although idea development discussions in groups have also been found to revolve strongly around feasibility (similarly to what happens in idea selection), groups should be especially suited for idea development if they bring their diverse cognitive resources to bear on the discussion (See Problem Solving).

Idea Implementation

The goal of idea generation, development, and selection is to turn ideas into actual products or procedures that can be sold or used – that is, idea implementation. Idea implementation is usually considered the end of the 'idea journey', where creativity turns into innovation. In reality, of course, even idea implementation can give rise to new ideas or further idea development: Whatever occurs or fails to occur as a consequence of idea implementation can be the starting point for a new creative process.

Problematically, idea implementation appears to be predicted by other variables than idea generation. For example, whereas external pressures decrease group (or team) creativity, they may contribute to successful implementation. Thus, what helps (or hinders) groups in their idea generation is not necessarily what helps (or hinders) them in implementing their ideas. Since the focus of (group) creativity research has largely been on idea generation, relatively little is known about the factors that predict successful implementation, but effective decision-making (i.e., idea selection) is an inevitable precondition. Because of the problematic nature of idea selection, the transition from creativity to innovation (that is, from idea generation to idea implementation) appears to be particularly challenging. Research on group and team innovation has predominantly aggregated innovative performance in measures that confound idea generation and idea implementation, but to the extent that these factors have been separated, group, team, or other social processes seem to be essential facilitators in moving towards successful implementation ([Somech and Drach-Zahavy, 2013](#)).

On the whole, then, although groups have undeniable creative potential, they often fail to live up to it. To a large extent, this seems to be due to their failure to make use of their cognitive resources. Ideas, perspectives, and opinions often do not get shared and processed effectively and efficiently. As such, the group creativity literature aligns well with the broader literature on group performance and group decision-making. For example, during decision-making tasks groups often discuss only knowledge that is already available to all group members, even if discussing unshared or unique information would demonstrably lead to a better decision. The discussion of task-relevant information, furthermore, can be superficial, and groups often fail to find optimal outcomes (such as integrative solutions in negotiations) even if all relevant information is available to all group members. Groups also often focus on reaching (and maintaining) consensus rather than on making the best possible decision, and often reject divergent information or viewpoints that threaten this consensus (especially when working under time pressure). Moreover, group polarization can lead to groups adopting an unnecessarily extreme viewpoint, which is not warranted by the opinions or knowledge of the individual members.

Nevertheless, despite the plethora of pitfalls that groups can fall into, the enduring popularity of group- and teamwork suggests that group creativity, for better or worse, is here to stay. The following section will discuss some general issues of how to organize creative group work effectively.

Designing Groups for Creativity

The literature on groups and teams is sometimes organized according to an Input-Process-Output framework, where Outputs are those variables that describe group or team performance – in this case, creativity. Input variables are those variables that describe what is 'given' about the group, such as group composition, group size, and characteristics of the group task. Process variables describe the things that go on in the group, such as communication, conflict and cohesion, and group climate and norms. Below, we discuss several Input and Process variables that affect group creativity.

Group Composition and Diversity

Obviously, group creativity benefits from having members with sufficient creativity-conducive traits and abilities. Personality, domain knowledge, creative skills, and motivation all contribute to each member's creative performance and hence might be expected to contribute to that of the group. This seems to be true to a large extent, although research also suggests that there is value in having (some) less creative group members (for example because these may be better equipped to safeguard a cooperative and systematic group process). Moreover, larger groups are not always more creative than smaller ones, even though a larger group should, all other things being equal, have a higher probability of containing at least some members with highly valuable knowledge, traits, or skills. For example, larger groups seem to be more susceptible to social loafing (where group members contribute less to the

group than they could, because their individual contributions are not identifiable and are perceived to be dispensable). Then again, larger groups potentially harbor a greater *variety* of knowledge, traits, and skills. Thus, beside the mere presence of certain member characteristics in the group, the way they are distributed and arranged in the group is a crucial aspect of group functioning as well.

However, group diversity actually is a double-edged sword: On the one hand, it is one of the reasons for using groups to begin with, but on the other hand groups often find it difficult to deal with. As a consequence, the effects of diversity on group creativity are inconsistent. Surface-level or demographic diversity (e.g., gender, ethnic, or age diversity) in particular can easily give rise to subgroup formation and, as a consequence, ineffective communication and information sharing within groups. Deep-level or cognitive diversity (which may or may not be aligned with surface-level diversity), on the other hand, is where groups' creative potential originates, but when left to their own devices groups usually fail to make use of this resource. Given that creativity, including creative decision-making, requires the integration and combination of diverse information, this obviously hampers groups' creative performance.

Whether or not groups are able to make use of their diversity depends on several factors, such as the diversity beliefs that group members hold: If group members have a strong belief that diversity is a valuable resource (rather than, say, a threat or a complication), diverse groups may perform more creatively than homogeneous groups, because they will be more willing to exchange and process diverse information and perspectives. Generally speaking, (cognitive) diversity *can* stimulate group creativity, if the group members are able and motivated to exchange and process their diverse (task-relevant) knowledge and ideas. However, field research also suggests that team diversity, although it can indeed stimulate creativity, does not automatically lead to successful implementation of the generated ideas.

Of course, group composition is not necessarily a given. Groups and teams change over time. This may also affect group creativity: For example, *newcomers* can bring previously unavailable knowledge or perspectives to the group. Some work suggests that such membership changes can indeed bring about or stimulate group creativity, but this depends on several boundary conditions including the characteristics of the newcomer, the stability of group membership, and group climate. Similarly to other forms of minority influence, a newcomer's ideas are not automatically attended to or valued by the rest of the team, but there is the potential for a newcomer to make a novel contribution that would not have been made otherwise.

Task Design and Interdependence

Besides selecting the right people for the group, for example those high in creativity or those contributing relevant and unique skills and insights, a fundamental way to enhance group creativity is through task design. A first, and relatively obvious principle is that the member resources (that follow from group composition) must be sufficient to match task requirements. If this is not the case, and important skills and knowledge are missing, it follows that either group composition must be changed or the task must be adjusted.

Secondly, at the individual level, the job characteristics model suggests that optimal task design includes 1) providing employees with sufficient autonomy, so they feel responsible for their job; 2) providing them with constructive feedback, so they know how well they are doing; and 3) giving them tasks that require varied skills, that are important to them, and that require the completion of a whole task (rather than only a part of it), so employees experience their work as meaningful. It is likely that these conditions will not only enhance work motivation and effectiveness of individual employees, but also of groups. For example, many organizations grant much autonomy to their teams, and research confirms that creativity and innovation are more likely to thrive in such relatively flat (as compared to more hierarchically structured) companies.

Thirdly, when it comes to team design, another critical task design feature is interdependence. Research distinguishes two types of interdependence. *Task interdependence* refers to the degree to which work is designed in such a way that members depend on each other for access to resources (e.g., information) and for coordinated action. *Outcome interdependence* refers to the degree to which outcomes of tasks are measured, rewarded and communicated at the group (rather than the individual) level. Research suggests that task interdependence creates a *need* for group members to cooperate, whereas outcome interdependence creates the *motivation* to do so. Because cooperation is crucial for groups to achieve high creativity, these two types of interdependence are extremely important.

Importantly, task and outcome interdependence are not necessarily aligned. It is possible, and relatively common, that group members have high task interdependence, but that feedback and rewards (e.g., promotion opportunities) are given to individuals and not the team. This is potentially problematic, because it creates a situation in which people have to collaborate, but may lack sufficient motivation to do so. Similarly, a combination of high outcome and low task interdependence creates problems, because people may have the motivation to work together but lack control over outcomes. Good task design thus requires that both types of interdependence are aligned. Following the principle that high group creativity requires an optimal combination of contributions of individual members, the alignment of high task and high outcome interdependence will stimulate cooperation and make it more likely that resources of the team members are used in an optimal way.

Group/Team Climate

Although properties of the group (e.g., composition) and the group task (e.g., interdependence) are important, some of the strongest influences on group creativity are found in the group process. These group or team processes, especially in organizations, are often described as *climate*, which is a shared set of norms and expectations regarding the way a team works. Climate factors are among the strongest predictors of group/team innovation, and the transition from idea generation to idea implementation crucially

depends on climate. Much of this work has used the Team Climate for Innovation model, which identifies four climate dimensions that contribute to group or team creativity and innovation (Anderson and West, 1996). Groups and teams perform more creatively and innovatively if they work towards a shared and valued goal, if new input and divergent opinions are welcomed, if innovative performance is the goal and the norm, and if the group is striving for excellent (innovative) performance.

Of these process or climate variables, *safety* – the degree to which members feel that their input is welcome – is particularly interesting, because its role is paradoxical. On the one hand, a safe group climate means that members can contribute without fear of negative evaluations or ridicule. A lack of self-censorship is a crucial precondition for creativity (and was one of the reasons Alex Osborn devised his classic brainstorming method). Thus, a certain sense of safety, group cohesion, or cooperation (as opposed to intragroup competition) is important. On the other hand, if safety and cohesion become dominant concerns, this could lead to group members holding back ideas or opinions that might cause conflict or dissent (in extreme cases, this could lead to forms of groupthink). This is particularly important in the context of group creativity, because novel ideas require a jump into the unknown and therefore are associated with uncertainty. In fact, organizational research suggests that employees who contribute and push for implementation of creative ideas are likely to experience more conflict with colleagues, because these creative ideas challenge the status quo.

A curvilinear relation between safety, creativity and innovation has been hypothesized, suggesting some optimal level of safety that is neither too low nor too high (Hülshager et al., 2009). Research suggested that groups perform most creatively when there is a mix of individualism (stimulating group members to develop their own, unique perspectives and ideas) and collectivism (motivating group members to contribute these perspectives and ideas for the benefit of the group). This tension between individualistic and collectivistic tendencies was addressed in a study which showed that minority influence (e.g., one group member disagreeing with the rest) can force the group to think about and discuss the task or task-relevant information more deeply (although this may require a high degree of participative decision-making), and may enhance divergent thought within the group. Moderate levels of task conflict may also contribute to group creativity or innovation, again because these can stimulate groups to engage in deeper information processing and more divergent thought – as long as the task conflict does not escalate and spill over into relationship conflict. Thus, creativity seems to require a group climate that is safe and cooperative enough for the individual member to challenge group members views and risk some conflict once in a while.

Other research that looked at different climate variables suggests that organizational teams perform more creatively when they have a strong promotion climate (i.e., focused on growth, attaining successes, and realizing ambitions) as opposed to a prevention climate (focused on safety, avoiding mistakes, and fulfilling responsibilities). Other group process variables that can affect creativity include reflexivity (the degree to which the group reflects on its own goals and strategies), communication both within and outside of the group or team, and conformity pressure resulting from a high need for closure (e.g., as a consequence of time pressure). If the group is strongly focused on making a quick decision, new information or divergent opinions are not welcome and will probably not get processed deeply.

Leadership

Finally, a great deal of research has considered leadership as an important determinant of group creativity. Even though organizations sometimes use leaderless teams (e.g., self-managed teams), most still include some form of leadership. Because leadership implies that those holding a leadership position have more power and influence than those who do not, characteristics and actions of leaders will have a disproportionate effect on creativity of the team.

There are two broad approaches to how leadership affects creativity in groups. The first looks at leadership styles. Most attention has been given to transformational leadership, which refers to a leadership style consisting of a combination of having an appealing vision for the group (e.g., be charismatic) and intellectual stimulation and taking care of group members. Not surprisingly, this leadership style will generally benefit group creativity, because it solicits the input of group members and unites them to try to achieve something great together. For example, it has been found that teams with transformational leaders are better able to reap the benefits of team conflict. A downside of this type of leadership is that it makes group members fairly dependent on the leader.

The second approach proposes that the task of leaders is to create the conditions for groups to be creative. In line with the discussion of designing creative groups, this approach suggests that leaders have to 1) make sure that they have the right people in the group; 2) create the right task conditions (e.g., interdependence structure); 3) create the right group climate (e.g., one in which members feel safe to express their unique insights). Other functions that leaders need to fulfill are ensuring that the group has sufficient resources, and monitoring progress and providing feedback to the group. This approach suggests that groups can be made more creative if leaders create the conditions under which group members can “do their thing” in an optimal way.

Conclusion

Groups have undeniable creative potential: The presence of a large and diverse store of knowledge, experiences, personalities and opinions can, in principle, make them extremely powerful sources of creativity. Whether or not groups live up to this potential crucially depends on the way they organize their work. When left to their own devices, it is all too easy for groups to fall into one of the myriad pitfalls associated with group work. However, under the right circumstances, including high levels

of task-relevant cognitive diversity coupled with effective leadership, favorable diversity beliefs and membership, moderate levels of task conflict, a strong motivation to process task-relevant information and a healthy mix of individualistic and collectivistic motives, groups have a lot to offer.

Glossary

Bipolar mood disorders A group of related mood disorders described in the American Psychiatric Association’s *Diagnostic and Statistical Manual of Mental Disorders*, fifth edition, (DSM-V) (2013). These can be serious, but they are also often effectively treated. Bipolar disorders are characterized by the presence of an episode of unusually elevated mood, but they typically also involve episodes of depression; these episodes of high and low mood frequently alternate with periods of normal mood. Several types of bipolar mood disorders can be distinguished. A strong familial liability to bipolar disorder is manifested in a wide range of psychiatric syndromes, from mild to severe.

Compensatory advantage In biology, there are examples of genes that increase vulnerability to illness but are also tied to positive characteristics. An example is sickle cell anemia, in which individuals who inherit a copy of the same mutant gene from both parents experience serious medical complications. In contrast, individuals who inherit only one copy of the mutant gene have milder symptoms and an important compensatory advantage: resistance to malaria. Several studies suggest that enhanced creative potential may be a compensatory advantage for genetic liability to schizophrenia and bipolar disorder.

Depression and unipolar mood disorders Unipolar disorders are characterized primarily by periods of unusually low mood, usually alternating with periods of relatively normal mood. Adverse effects of depressed mood on other psychological functions are also typically present, such as disturbances in sleep, appetite, and energy. These mood disorders can range from major or severe depressions to milder ones. These disorders can be extremely serious, but effective treatments are often available.

Schizophrenia spectrum disorders Schizophrenia is a psychotic disorder characterized by periods with two or more of several key symptoms: delusions, hallucinations, disorganized speech or behavior, and negative symptoms, such as diminished emotional expression and initiative. These symptoms also cause significant dysfunction in areas such as work and

interpersonal relations. Biological relatives of schizophrenia patients also tend to have higher rates of milder disorders and schizotypal symptoms such as odd ideas and unusual perceptual experiences.

Introduction

This chapter discusses research findings on several of the many ways that creativity and health influence each other. Research indicates that creative activities, therapies, discoveries, and problem-solving are important for understanding, treating, and preventing medical disorders. But while creativity is important for improving mental and physical health, so too is health important for fostering creativity (Richards, 2014; Kinney and Richards, 2014).

We will focus on four particularly important sets of questions about how health and creativity interact. First, can creative activities and therapies improve negative moods and clinical depression? This is important because *major depression is an especially serious health problem*: depression is a major risk factor in suicide, and many medical disorders. The WHO estimates that major depression is also the leading cause of disability in the peak years of working and caring for families.

Second, how are health and certain mental illnesses related to creativity? Is creative genius more common in people with mood and schizophrenia-related disorders – and if so, why? Do genes that increase liability for these disorders also increase creative potential?

Third, how can we encourage creative problem solving that leads to new medical discoveries? It's a crucial question, because medical breakthroughs are crucial for improving health of people with *many different* physical and mental disorders.

Fourth, can research on creative problem-solving and negotiation unite diverse people to find win-win solutions for the most threatening global health problems – such as infectious disease pandemics, and mass extinction of species – that would severely damage health of both people and animals for many generations?

Can Creative Activities and Therapies Improve Mood as Well as Mental and Physical Health?

Several lines of research provide evidence that engaging in creative activities can help raise people's mood and combat depression. For example, Silvia et al. (2014) studied young adults' activities and feelings at randomly sampled times over the course of a week. The researchers found that when people were doing creative activities such as writing or drawing, they reported feeling happier on average. This study was correlational, however, so it is difficult to be certain about causal relations between creativity and mood. Other studies have used *experimental* research designs, where one can be more confident about *causation*.

Ellen Winner and colleagues conducted several such experimental studies on how creative activity affected temporarily depressed mood in healthy children or college students. They found that students' mood was more likely to improve if they were assigned to engage in certain types of creative activity. For example, DePetrillo and Winner (2005) found that being asked to do creative artwork elevated in depressed mood in students whose sad mood was induced by watching distressing videos.

Another experiment tested whether *art therapy* improved mood in depressed patients (Blomdahl et al., 2018). In addition to standard treatment, patients were assigned at random to receive, or not receive, manual-based art therapy that asked individuals to paint pictures based on their personal goals. Patients who received art therapy had significantly greater reduction in depression than controls without art therapy. These promising findings need to be confirmed in new studies.

Complementary research suggests creative therapies could also improve *physical health*, because multiple studies found that depression is associated with increased risk for many serious medical disorders such as heart disease and diabetes. Niles and O'Donovan (2019) analyzed longitudinal data on more than 15,000 older adults, finding that depression increased risk illness as strongly as, or even more strongly than, obesity and smoking.

Depression also tends to induce depression in depressed patients' *relatives*. For example, if mothers are suffering from postpartum depression, their infants are also more likely to become depressed; treating depressed mothers also relieves children's depression. Bipolar disorders and schizophrenia are also associated with increased rates of suicide and certain medical disorders. Creative therapies might therefore help many different mental and physical disorders.

Is Creativity Related to Certain Mental Disorders and Genetic Liability for These Disorders?

Overview

Are genius and madness related? Many scientific studies have found evidence for significant relations between creativity and mental illness and/or genetic liability for certain mental disorders. The strongest associations with creativity involve bipolar disorders and schizophrenia – and genes for those disorders. Highest average creativity is found, *not* in individuals with severe

symptoms, but rather in their *healthier relatives* who may carry genes for these disorders. These genes in turn may be associated with unconventional ways of perceiving and thinking about the world – ways that help generate novel ideas that lead to creative breakthroughs.

Research on creativity and *mood* disorders, including bipolar disorders and depression, is discussed in more detail in the chapter on **Bipolar Disorders** in this encyclopedia. We therefore will consider key points on those disorders rather briefly here, before turning to a longer discussion of creativity and schizophrenia spectrum disorders.

Creativity and Mood Disorders

Several studies of eminent creators in art, literature, and music found higher rates of mood disorders among these creators (e.g., Jamison, 1989). Further research indicates this is *not* the result of beneficial effects of extreme moods on creativity. Rather, eminent creators report their *most creative* periods are associated with episodes of mild or moderate mood elevation; extreme moods such as mania and major depression actually interfere with creativity. Complementary evidence found that, on average, the greatest creativity in people's job and hobbies is found in the *healthier* biological relatives of people with bipolar disorder, rather than either people with frank bipolar disorder, or people with no personal or family history of mood disorders (e.g., Richards et al., 1988; Kyaga et al., 2011).

Schizophrenia and Schizotypal Symptoms

Research on the relation of creativity to schizophrenia and milder “schizophrenia spectrum” disorders found parallel results: symptoms of full-blown schizophrenia – such as hallucinations and delusions, or deficits in thinking, attention, and initiative – are associated with *lower* creativity. By contrast, *healthier* biological relatives of schizophrenia patients tend to have *more* creative job and hobbies than people with no personal or family history of mental disorders (e.g., Kyaga et al., 2011). Similarly, individuals with schizotypal personality disorder or schizotypal signs – unusual types of thinking and perception more common in biological relatives of schizophrenia patients – tend to report more creative jobs and hobbies than control subjects (e.g., Kinney et al., 2001), and score higher on creative thinking tests (Folley and Park, 2005).

Other studies found that certain genes that increase risk for developing schizophrenia or psychosis also are associated with increased creativity in individuals who carry the genes but don't develop frank schizophrenia (Keller and Visscher, 2015). This increased creative potential may be a “compensatory advantage” for the genes, which helps explain why the genes – and severe disorders they may help produce – persist in the population, despite the fact that people with schizophrenia are less likely to have children (Kinney and Richards, 2014).

Creative Problem Solving, Unconventional Ideas, and Revolutionary Advances in Healthcare

We will now shift to *different* ways in which creativity can have important effects on health. *Generating creative ideas* is crucial for *discovering new ways to understand, treat, and prevent diseases*. This process works best when curiosity and openness to considering – and testing – new ideas. A paradox in scientific discovery is that the most important new ideas are often ones that challenge conventional thinking – and that therefore often initially receive severe criticism – even ridicule. Let's consider two important examples in medicine.

Australian physician Barry Wallace shared a Nobel prize for discovering that many peptic ulcers are caused by an infection with the bacterium, *H. pylori*. Ulcer specialists initially dismissed Wallace's theory, because conventional wisdom held that stress caused ulcers and bacteria could not survive the stomach's acidic environment. Wallace persisted, showing that *H. pylori* thrives in acidic conditions, and antibiotics that killed *H. pylori* often cured ulcers.

A second example illustrates how creative breakthroughs – because they often involve radically new ways of thinking about health problems – sometimes come from people outside a medical field. A revolutionary device for more safely delivering babies was invented, not by obstetricians, but Argentine auto mechanic, Jorge Odon. Odon's device is potentially the most promising advance in decades for treating obstructed labors that kill thousands of infants and mothers each year.

Note, however, that most unconventional ideas don't work. Developing a theory or invention typically requires winnowing good ideas from bad ones, and extensive testing and modification until a good working model is reached. Uncritical acceptance of unconventional ideas can be dangerous. For example, epidemiologists concluded that over 300,000 South Africans died from AIDS because one president, Thabo Mbeki, believed a discredited theory that HIV didn't cause AIDS, so he blocked lifesaving programs that use antiviral medications to treat HIV (Chigwerdere et al., 2008).

Creative “Win-Win” Solutions to Successful Negotiation and Breakthroughs in Healthcare Advances

Research on Steps in Creative Problem-Solving and Successful Negotiation That Lead to Win-Win Outcomes

Some of the most important advances in healthcare involve the development of creative “win-win” policies and programs that simultaneously advance the key interests of groups with different agendas. Decades of research on negotiation by Harvard Law

professor Roger Fisher and his colleagues identified several key steps in achieving the ideal outcomes that leave both parties a) believing their key goals have been significantly advanced and b) having positive feelings for each other.

A key step is actively searching for these creative win-win solutions that help advance key interests of *both* parties. To find these win-win solutions involves entering the negotiation with an open mind about possible solutions – a key point, because the research found the *best outcomes* were usually *creative ones* that never occurred to either party before the negotiation began.

Let's now consider two examples of how creative problem solving and negotiation – and the search for win-win solutions – can be key factors in reaching the best outcomes for the world's most important health problems. Win-win outcomes from creative negotiation can be even more important than creative discoveries of cures for a single illness, because a win-win outcome can simultaneously help solve not just one, but *many different medical problems*.

Better Prenatal Care: A Win-Win Strategy to Save Lives, Improve Children's Long-Term Health, and Prevent Unnecessary Healthcare Costs

A long-standing debate – particularly heated in the US – involves how much governments should spend to ensure that all their citizens receive good quality healthcare. One view is that providing high-quality healthcare is of prime concern. A competing view is that curbing increasing healthcare costs is more important.

A win-win strategy to help address this dilemma is indicated by scientific evidence that *quality prenatal health care* – such as pregnant women's access to good healthcare and nutrition, and protection against infections, chemical toxins, and maternal emotional stress, saves lives and money *in many different ways*. It reduces fetal, infant, and maternal death rates. In addition, analyses by economists Almond and Currie (2011) found that spending money on better prenatal care is a highly cost-effective way to promote people's mental and physical health. Improving prenatal care is cost-effective because the intervention period is relatively brief, and the better health outcomes for children can last a lifetime, reducing healthcare and social welfare costs for decades, and making people healthier and better able to work and contribute to economic health of society.

Protecting Endangered Species and Wilderness: Creative "Multi-win" Ways to Protect Human and Animal Health, Discover Breakthrough Drugs, and Prevent Infectious Disease Pandemics

An even more important kind of win-win approach could improve health a) not just of one country, but of people around the world, b) not just of people alive today, but of countless future generations of people, and c) not just of human beings, but of millions of animal species threatened with extinction. Nobel-Prize-winning physician Eric Chivian (2012), reviews evidence of the vital importance for *human health* of protecting animal species from extinction. Protecting these species is the best way to protect animals' rights, but mass extinction also threatens *people's* health. Other species have evolved the capacity to survive infections and other illnesses that kill millions of people. These species thus have medical secrets for how to treat and prevent human illnesses; if these animals go extinct, we will lose their secrets forever.

For example, *current antibiotic drugs* save millions of people's lives, but they eventually no longer work, because bacteria develop genetic resistance to the drugs. Yet some species of frogs produce antibiotics to which germs don't develop resistance. Understanding how frogs do this would save countless human lives. Opioid drugs provide critical pain relief, but they also can cause addiction, killing millions of people each year, and opioids can lose their pain-reducing power because patients develop tolerance to the drugs. Chivian notes the first drug with the pain-relieving potency of opioids, but without their addictive and tolerance problems, was derived from a toxin produced by predatory cone snails. These snails have evolved more than 100,000 specialized neurotoxins (to kill prey) that are more sensitive and targeted than drugs we now have. These neurotoxins may be the most valuable pharmacopeia on earth, but their medical secrets may soon be lost, because most cone snails live in coral reefs that climate change is beginning to kill.

Infectious disease pandemics such as AIDS and Ebola have killed millions of people. These epidemics began when humans contracted novel infectious agents from contact with wild animals in wilderness areas. These infections are often particularly deadly to humans because human populations lack previous exposure and have developed little genetic resistance to the infectious agents. One of the most *creative and effective* ways to protect present and future generations from new epidemics is protecting wilderness areas and wildlife from encroachment by people.

Optimistic Win-Win Implications of Research on Creativity and Mental Disorders

Research discussed earlier on creativity and liability for mental disorders has optimistic implications. Treating patients' symptoms is a win-win approach: a) helping patients and their relatives realize their unusual creative potential, while also b) helping to increase the self-esteem of patients and their relatives, and c) fighting the stigma often attached to the disorders. The world desperately needs more creative solutions to daunting problems – such as nuclear war and climate crises. The unusual potential for great creativity carried by many bipolar and schizophrenia patients – as well as their biological relatives – is a precious natural resource for developing creative solutions to these crucial problems. Therapists and educators – through appropriate medical and counseling support for these talented but vulnerable individuals with genetic liability for schizophrenia or mood disorders – may help realize that untapped creative potential, to the enormous benefit of the world, as well as the patients and their families.

Conclusion

We have discussed research on several of the most important issues involving creativity and health. Let us now review the key research findings that help answer the four sets of questions we posed at the beginning of the chapter.

Can Creative Activities and Therapies Help Combat Depression as Well as Other Serious Medical Disorders?

Evidence from several complementary lines of evidence indicates that creative activities and therapies can improve mood and fight depression. Experimental studies of college students, as well as a clinical trial with depressed patients, found that creative activities and art therapy respectively elevated mood. Complementary research suggests that creative therapies that lift mood could also prevent other disorders, because major depression increases risk for these disorders. More research is needed to confirm these findings.

Is Enhanced Creativity Related to Certain Mental Disorders or to Genetic Liability for These Disorders?

Research on this question suggests that the strongest associations of creativity with mental disorders involve bipolar disorders and schizophrenia – and genes for those disorders. Higher levels of creativity tend to be found, *not* in individuals with the most severe forms of these disorders, but rather in their *healthier relatives* who may carry certain vulnerability genes for these disorders. These genes in turn are associated with unconventional ways of perceiving and thinking that help generate unusual ideas that aid in developing creative breakthroughs. These results have *optimistic clinical implications*. For example, therapeutic support for people who carry these genes could prevent carriers from becoming ill and also help them realize unusual creative potential. These research findings also can help fight stigma and encourage patients to seek and maintain treatment.

How Do Unconventional Thinking and Creative Problem-Solving Help People Make Important Medical Discoveries?

Creative breakthroughs often come from people whose ideas so challenge conventional wisdom that they are initially treated with skepticism, as with the Nobel-Prize winner who discovered that a type of bacteria helps cause ulcers. Some breakthroughs even come from people *outside* a medical field, who can view problems from a fresh perspective, as with the auto mechanic who invented a potentially safer device to deliver infants. These findings have important *implications for aiding the discovery of new medical breakthroughs*, such as encouraging greater openness to testing theories that challenge conventional wisdom, and encouraging greater diversity of people in a medical field, because having people from diverse backgrounds often aids in generating creative new ideas.

How Can Creative, “Win-Win,” Ideas Help Solve Daunting Health-Care and Environmental Problems to Produce Revolutionary Advances in Global Health?

Creative problem-solving and negotiation among different people can lead to “win-win” solutions to some of most dangerous threats to global health. For example, protecting endangered species and wilderness areas can help prevent global infectious disease pandemics that have been some of the greatest causes of death in human history. This win-win approach can also protect millions of species from extinction and, in so doing, prevent us from losing the valuable medical secrets that those species can teach us, such as how to develop pain-killing drugs that are not addictive and to which people don’t develop tolerance. Such creative negotiating approaches to finding win-win solutions are also needed to solve other serious health problems, where different groups of people may have different values and priorities. Avoiding zero-sum thinking and searching for creative win-win solutions can help us overcome political deadlocks to solve many other challenging health problems.

The way we conceptualize creativity today, as something both new and useful (Kaufman, 2016a), is the result of a long and complex history (Glăveanu and Kaufman, 2019). Understanding how our concept of creativity has developed over the ages is important for grasping the issues creativity researchers are facing today. One issue that will become apparent from this review is the historical focus on the creativity of men in Western civilizations. Another one is that although creativity research appears to be a ‘child’ of the 20th century, in particular its second half, the paradigmatic ways in which we understand creativity to this day have deep historical roots. It is important to note that we will focus mostly on the Western history of creativity. There are, undoubtedly, other histories of this phenomenon to be written, such as from an Eastern or a Global South perspective, and it would be interesting in the future to notice the commonalities, differences, and crossovers between these different cultural spaces when it comes to creating and creativity.

Biblical Times

During the biblical ages (and through the Middle Ages) all creativity was attributed to God (or gods, depending on the religion). According to the Bible, creativity was inextricably linked to the divine, because God created human beings and commanded their acts. Thus, all creation came directly from God, “The Creator”. Many early philosophers believed that it was not possible for a human being to create or experience anything new at all; Ecclesiastes (1:9), for example, claimed that there was “nothing new under the sun.” They considered all human activity to be an imitation of the divine and suggested that attempting to produce novelty only demonstrates our “vanity.” Similarly, in ancient Greece and Rome, creative acts were attributed to the gods or god-like beings. According to Plato, the Muses possessed poets in order to bring forth works that they could not achieve as mere humans. Aristotle suggested that all art was imitation of nature, created by the gods. Interestingly, thus, creativity did not originate for people living during Antiquity within the person but came from the outside, a conception that remains to this day in the way we sometimes conceive of inspiration. The concept of creation as inspired by and credited to God (or gods) continued into the Middle Ages and only came under scrutiny during the Renaissance.

The Renaissance

The Renaissance was a time of substantial invention and progress. It was during this time that it first became acceptable to attribute creativity to human beings. This was a revolutionary shift in the history of Western civilization – one that had long-lasting consequences not only for how we conceive of creativity, but also how we consider human agency and its relation to others and to society. During the Renaissance, men (and less so women, due to ideological reasons) started to place themselves at the origin of creativity, replacing God as the one and only creator. Interest for this kind of human creativity flourished. Artistic work was originally commissioned, for instance, by the church or by wealthy patrons. Over time, the visual arts were distinguished from crafts and technology, which were viewed as not originating from one’s creativity, and became allied with poetry as a creative art form. It was also during this time that artists began signing their artwork and independently creating (without the support of wealthy patrons) and selling their own work. Creativity in other areas, rather than just the arts, began to be recognized, such as in the sciences and invention.

The Enlightenment

The Enlightenment brought even further acceptance and encouragement of creativity, "... focused on change, the emergence of the new, through ordered progress, rather than through spontaneity" (Weiner, 2000, p. 71). European governments established incentives and awards for individual creators, and scientific and technological advances were plentiful (e.g., the steam engine, railroad, and gas lighting). Society began to grant rights to individuals regarding their creations, establishing patents and copyrights. It was during this time that the novel was invented, and the first museums opened. Defined by an ethos of conquering nature, including by constructing rational models of it, this period's view of creativity was that of an orderly process that could be explained causally, just like any other phenomenon. Although the Enlightenment was foremost characterized by the importance of order and rationality in creation, this ideal changed drastically during the Romanticism.

The Romantic Era

During the Romantic era, creativity came to be thought of as an innate ability, stemming from instinct and emotion, leaving little room for rational processes. As such, self-expression and imagination in the arts were highly valued. By the 19th century, genius as an individual attribute was largely thought to be hereditary. The idea of a link between genius/creativity and madness was widely popular at the time due to the fascination with the bizarre, the inexplicable, and the limits of human rationality (Becker, 2014). Attempting to separate from the past (i.e., the ideals of the Enlightenment) and distinguish themselves from the common man, the Romantics emphasized irrationality: "It was the aura of mania that endowed the genius with a mystical and inexplicable quality that differentiated him from the typical man, the bourgeois, the philistine, and the merely talented" (Becker, 2001, p. 48). The classic Romantic myth of Frankenstein emphasizes the genius of the creator and the madness brought by his own creation (once more, the focus at this time remained primarily on male creativity). Belief in a creativity-madness association is still common and is especially strong for certain creative domains (e.g., poetry). Although not without controversy, most creativity researchers today agree that the evidence for any real connection between creativity and mental disorder is lacking (see Taylor, 2017).

The 20th Century

During the early 1900s, some of the most influential theorists in psychology wrote about creativity. However, these writings were mostly tangents for those examining mental illness, child development, or gifted education. Sigmund Freud discussed creativity in the context of mental illness, suggesting that creative writers were engaging in fantasy because they were dissatisfied with life. He warned that over-indulging in fantasy would lead to psychosis or neurosis, which both result in a break from reality (though with different underlying causes). Lev Vygotsky discussed creativity in the context of child development, suggesting that children's play is a creative act because they use their imagination to create new meaning from real experiences. During this time, it was rare for creativity to be studied for its own sake.

In 1950, J. P. Guilford, who had just been elected president of the American Psychological Association, gave a speech urging psychologists to study creativity and the creative process. His focus was on understanding individual differences in creativity, or "the abilities that are most characteristic of the creative person" (Guilford, 1987, p. 33). He suggested that creativity was a form of problem solving, which depended on a person's ability to recognize problems (sensitivity), quickly generate ideas (fluency), and adapt to spontaneously produce responses that were both original and high quality (flexibility). Guilford's model of the structure of intellect suggested that all mental abilities are the result of different combinations of cognitive operations, contents, and products. Based on this idea, he distinguished between two different types of thinking and approaching problems: divergent thinking and convergent thinking. Divergent thinking involves generating as many ideas or solutions to a problem as one can and convergent thinking involves narrowing down ideas and solutions by discarding inappropriate or less desirable ones. Divergent thinking is most often associated with creativity by both the public and researchers, and tests developed to measure divergent thinking are still frequently used today. One that is frequently used is the Alternate Uses Task. The AUT asks participants to list as many uses as they can for a common item (e.g., a paperclip or newspaper). The responses are then scored on four factors that Guilford suggested underlies divergent thinking: fluency (the number of responses), flexibility (the number of categories of responses), originality (the uniqueness of responses), and elaboration (the detail provided for responses). Although divergent thinking is frequently used as an indicator of creative potential, Guilford stressed that both divergent and convergent thinking processes were necessary for creative thought and there is some controversy over how much divergent thinking ability relates to creativity.

Guilford's speech coincided with a cultural shift in the United States, which marked a newfound focus on individualism and creative potential. Thus, the 1950s marked the beginning of modern creativity research, and in the decade or two following Guilford's theories, several other theoretical and empirical developments began emerging across many different aspects of creativity. In 1961, Mel Rhodes examined how creativity was being studied. He identified four categories, or strands of research, in the existing literature on creativity. Most creativity research conducted during the mid to late 20th century can be described in terms of these categories, known as the Four P's: Product (the characteristics that make a product creative), Person (the individual differences

that characterize a creative person), Process (the processes underlying creativity), and Press (how the environment influences creativity).

The Creative Product

In early attempts to rate the creativity of a product, researchers proposed criteria based on specific dimensions they believed to be important for creativity (e.g., originality, humor, effort; see Besemer and Treffinger, 1981). The criteria set by individual researchers differed across studies, making it difficult to compare findings and muddying the concept of what constitutes a creative product. In one review, researchers found more than 125 specific criteria that had been used in studies to assess the creativity of a product (Besemer and Treffinger, 1981). However, the criteria used in early studies can be distilled down to two: novelty and appropriateness (though some earlier studies also incorporated elements of style or aesthetic considerations). Indeed, the definition of creativity as something “novel and appropriate” had become popular among creativity researchers before this time. That a product must be novel, or new, to be creative is somewhat intuitive. Perhaps for this reason, more research and public attention has been paid to the novelty component of creativity. However, the appropriate or usefulness component is also necessary for a product to be considered creative (Kaufman, 2016). Without novelty, an idea or product is mundane, but without appropriateness, it is nonsense.

In the latter part of the 20th century, with a growing focus on socio-cultural creativity, Teresa Amabile created the Consensual Assessment Technique (CAT). The CAT, which is based on the premise that the subjective creativity ratings of those in a given field are more similar to the way creativity is judged in real life, entails having multiple individuals with some degree of expertise in an area rate the creativity of products created by participants (e.g., poems, drawings, mathematical equations). Importantly, the raters are not given a formal definition of creativity but are asked to use their own understandings of the term. If the ratings demonstrate sufficient inter-rater reliability (i.e., the pattern of ratings is similar across judges), the sum or average of the ratings can be used as an indicator of creativity. The CAT is the most widely used method of assessing the creativity of a product.

The Creative Person

Much of the theory developed following Guilford’s speech focused on the characteristics that make a person more-or-less creative. Sarnoff Mednick’s theory about how individual differences contribute to creativity were based on his Associative Theory (1962), which suggests that creative ideas are the result of combining existing concepts in our semantic memory (i.e., learned knowledge). Because to be creative an idea must be novel, more creative ideas come from combining less obviously related (i.e., more remote) concepts. Mednick suggested that people who are able to combine more remote concepts to form ideas have relatively broader associative hierarchies (i.e., concepts stored in their memory are loosely associated with a wider variety of other concepts, rather than being strongly associated with a few). Mednick’s Remote Associates Test (RAT; Mednick, 1962) is based on this theory, and is still widely used today. The RAT asks a person to provide the one word that relates to each of three given (conceptually distant) words (e.g., providing the word *bag* when given the words *sleeping*, *bean*, and *trash* = *beanbag*, *sleeping bag*, *trash bag*). Gerald Mendelsohn later suggested that, rather than being based on fixed associative hierarchies, individual differences in the ability to combine remote concepts is due to a broad (as opposed to narrow) focus of attention (i.e., the ability to hold relatively more concepts in your mind at once). According to this view, a more creative person has more concepts in their mind simultaneously, increasing the odds of combining concepts in new ways.

Many researchers (such as Guilford) believed that creativity was a component of intelligence. However, E. Paul Torrance suggested that creativity and intelligence were distinct abilities and proposed the Threshold Hypothesis to explain how creativity relates to intelligence. The Threshold Hypothesis suggests that a moderate level of intelligence is necessary to be creative, so intelligence and creativity should be moderately correlated up to a certain point (e.g., an IQ of 120). However, after reaching this threshold, they should no longer be correlated. He built on earlier work on the role of divergent and convergent thinking in creative ability to develop the Torrance Tests of Creative Thinking (TTCT). The TTCT asks participants to complete a series of figural and/or verbal tasks, such as completing drawings using two parallel lines or coming up with many different consequences for an unlikely event (like rope hanging from clouds). A series of longitudinal studies, beginning in the 1950s and spanning 50 years, demonstrated that ones’ performance on the TTCT as a child could predict later creative achievement and accomplishment better than general intelligence. Although the TTCT remains a popular way to measure creativity today, there is some debate about how well divergent thinking relates to creative achievement.

Examining the issue of what makes a person more-or-less creative from a different perspective, researchers at the Institute of Personality Assessment and Research (IPAR) at UC Berkeley worked to create measures examining the personality and individual difference variables related to creativity. One measure, Harrison Gough’s Creative Personality Scale (CPS) is a self-report checklist that asks participants to select which items apply to themselves from a list of adjectives found to distinguish between people who are creative (e.g., clever, resourceful, and unconventional) and those that are considered to be not creative (e.g., conservative, submissive, and commonplace). The Barron-Welsh Art scale was created based on Frank Barron’s research, which demonstrated that artists and other creative people prefer complex, non-symmetrical figures. Participants indicate which of a series of figures they like and dislike and receive higher scores for liking figures that are complex and non-symmetrical. Although these measures are still used by researchers today, the Five-Factor Model of personality has been used the most to study how personality relates to creativity. Openness to experience has been the strongest and most consistent predictor of creativity out of the five traits (i.e., extraversion, agreeableness, emotional stability, conscientiousness, and openness to experience).

The Investment Theory of Creativity (Sternberg and Lubart, 1992) was developed based on Robert Sternberg's idea that a certain cognitive style, intelligence, and personality/motivation is necessary for a person to be creative. This theory suggests that recognizing ideas that are undervalued and convincing others of their value (skills needed to be a successful creator) requires a person to have the appropriate motivation, intelligence, knowledge, personality, thinking styles, and environment. This enables them to recognize, develop, and sell (persuade others about) their creative ideas.

The Creative Process

The creative process, the mental processes by which creativity occurs, is suggested to progress through a series of stages. Graham Wallas (1926) proposed a well-known five step model of creativity which included the stages of preparation, incubation, insight, verification, and elaboration. Preparation (defining a problem and gaining relevant knowledge), verification (selecting the best ideas), and elaboration (bringing an idea to fruition and evaluating its usefulness) refer to conscious, effortful processes. However, the incubation stage is characterized by the unconscious "forming of associative elements into new combinations" (Mednick, 1962, p. 221) that occurs when an individual is either in a relaxed state or working on a non-related problem. This associative processing leads to the insight stage, the moment when the idea reaches consciousness, in a moment of sudden insight (Wallas, 1926).

Wallas' model is still used by modern researchers and many models have been developed by expanding on these concepts. In general, these models continue to suggest three phases: 1) a preparation/problem recognition phase, characterized by gaining the knowledge and experience necessary to recognize that a problem requires a creative solution and to form creative ideas; 2) an inspiration and generation phase, characterized by forming or discovering a creative idea; and 3) a verification and implementation phase, characterized by the evaluation and implementation of an idea.

Alex Osborn (1953) suggested that idea generation may be enhanced by brainstorming, allowing a group of people to offer any possible relevant ideas or solutions to a problem without the danger of being criticized. The main assumption in brainstorming is that quantity (as in number of ideas) will lead to quality. Although brainstorming continues to be used today, there are a number of factors that can limit its effectiveness (Paulus and Brown, 2007).

Theories of the way people get and evaluate ideas that were created later in the 20th century include the Geneplore (for generate-explore) model and Simonton's Blind Variation and Selective Retention theory. Simonton's theory suggests that created ideas are generated by a random combination of conceptual elements, which are subsequently retained or eliminated, similarly to the process of natural selection.

Both the general public and scientists have traditionally focused most attention on the inspiration phase, because it aligns more with the colloquial meaning of creativity (as ideation and the "aha!" moment of inspiration). However, creativity researchers are becoming increasingly more interested in understanding the preparation, problem recognition, and implementation phases.

The Creative Press

Although there was talk about examining creative press (i.e., external factors that influence creative production) during the time Rhodes (1961) conducted his review, theories incorporating the role of social context did not begin to emerge until the 1980s. Key to this development was Teresa Amabile's (1983) Componential Theory of Creativity, which suggests that creativity depends on domain-relevant skills, creativity-relevant skills, and task motivation. In a series of studies, Amabile demonstrated that an individual's creative performance can be diminished by external factors that affect task motivation (such as the threat of evaluation). For example, creative writers who were asked to write a haiku-style poem after listing intrinsic reasons for writing creatively (i.e., reasons related to enjoyment or personal fulfillment) wrote significantly more creative poems than those asked to list extrinsic reasons (i.e., reasons related to external reward or punishment) and a control group.

Mihaly Csikszentmihalyi's Systems Model represents an even more contextual perspective of the role of the environment in creativity, looking at how the person, field, and domain influence one another. He suggested that because the gatekeepers in a field (i.e., the people in positions of authority who promote, evaluate, or recognize creativity) change, how a creator and his or her work are viewed in a given time and place changes. The domain or the cultural areas that welcomes what is being created also changes over time and across contexts. As such, the domain and those involved (i.e., practitioners and consumers) influence both how the work is viewed and the creator's subsequent work.

Creativity Today

Creativity research grew substantially in the latter part of the 20th century (and into the 21st century), leading to a more nuanced understanding of creativity and how its different components relate to one another. Research now frequently studies how the categories within Rhodes's (1961) 4Ps framework (i.e., person, process, product, press) interact. Vlad Glăveanu (2013) presented an updated framework, the Five A's, to account for the greater complexity of creativity research and theory today. The Five A Framework re-conceptualizes the categories of creativity research as actor, action, artifact, audience, and affordance. Actor refers to personal attributes (i.e., person) in relation to a sociocultural context, because the sociocultural context in which we are socialized influences the ideas we generate and how we present them to others. Action refers to creative activities (i.e., process) directed by goals, which are influenced by a particular context and rely on a series of external and internal feedback loops (instead of being a linear series of

stages). Artifact refers to how creations (i.e., product) are influenced by personal interpretations of sociocultural symbols that connect people through a shared sense of meaning. Audience refers to others in our environment (i.e., press) that influence creations (e.g., assisting, being inspired by, consuming or rejecting a creation). Affordance refers to how the materials and limitations of the physical environment (i.e., press) influence our opportunities for creating.

Researchers have also begun to delve into the complexities of the construct of creativity itself. Building on the concept of the distinction between Big-C (creative contributions that make lasting and far-reaching impact) and little-c (creative behaviors and activities that people may engage in during daily life), James Kaufman and Ronald Beghetto proposed the Four C theory of creativity to incorporate a more complex understanding of the different levels of creativity and how they might develop. Mini-c creativity, which occurs when someone has an insight that is personally meaningful and new to that person, can evolve into little-c, which is recognized as creative by other people, with feedback and guidance. It can then evolve into Pro-c, professional or expert creativity (Kaufman and Beghetto, 2009), with years of deliberate practice. It may further develop into Big-C or historically recognized creativity, though this occurs for relatively few people and is usually posthumous.

Additionally, creativity researchers began developing models to reconcile the concepts of creativity as a general ability that is the same across all contexts (domain general) and creativity as an ability that differs from one area to another (i.e., painting vs. physics; domain specific). For example, James Kaufman and John Baer proposed the Amusement Park Theoretical model (APT; Baer and Kaufman, 2005), which uses an amusement park metaphor to describe how creativity contains elements of domain generality, but becomes increasingly more specific within different domains. Just as a person must have an admission ticket and transportation, a potential creator must meet certain initial requirements (e.g., sufficient motivation and cognitive ability) in order to be creative. If these initial requirements are met, a person must decide which type of amusement park to go, just as someone must decide which general thematic area (e.g., arts or sciences) in which to be creative. A person must then choose a park in that area, just as one must choose a specific creative domain (e.g., painting vs. sculpture) in which to be creative. Finally, a person must choose which activity or ride to go on at the park, just as one must choose a microdomain (e.g., landscape vs. abstract painting) in which to be creative.

Concluding Remarks

Our understanding of creativity has continuously changed through the ages, and will no doubt continue to evolve. This review highlighted the historical origins of our modern conceptualization of creativity and how its development has been influenced by the changing socio-cultural circumstances and ideals of society. It is important to note here that our view of creativity, at least in the West, went through several stages of gradual ‘internalization’ (i.e., of making creativity an intra-psychological phenomenon). The Renaissance and Romanticism contributed greatly to this major conceptual shift from creativity understood as the feature of gods or the collective, for example various guilds, and towards creativity as a personal trait, something that special people truly ‘possess’.

A second major change had to do with how inclusive or restrictive the notion of creativity was through the centuries. If in antiquity the notion of genius was used to designate the protective spirit of a place or family, the word genius today has a much more exclusive connotation. From the 1950s onwards, however, we are witnessing a ‘democratisation’ of creativity through an emphasis on creative potential assumed to be characteristic for each and every individual – once more, it is the person and not the collective coming to the front.

The recent development of psychometric tests of creativity, at the scale of history, capitalized on both these historical trajectories. It is a 2nd century of interconnectivity and interdependence that brings back systemic or distributed approaches to this phenomenon and advance our understanding of it. The history of creativity is, in many ways, the history of humanity. What we create, individually and collectively, not only makes history but the development of our societies and its new directions feed back into how we think about and ultimately how we study and practice our own creativity.

Background

Historiometric research examines the big names and important happenings that can be considered historic in the sense of “making history.” For example, the subjects of historiometric studies may involve eminent artists, writers, or scientists (e.g., Leonardo da Vinci, Cervantes, or Einstein) or they may entail major acts of creativity such as musical masterworks or major scientific discoveries (e.g., Beethoven’s Fifth Symphony and the heliocentric theory of Copernicus).

The database concerning these historic subjects is compiled from various archival sources, such as histories, biographical dictionaries, encyclopedias, anthologies, and collections. The data may also be derived from the content analysis of creative products, including the computer analysis of music and literature. Because historiometric research concentrates on individuals or products that are highly distinguished, the archival information on these cases is often extremely rich.

The goal of the study is nomothetic rather than idiographic. Nomothetic research involves the quest for general psychological laws or patterns, whereas idiographic research concentrates on those features that are unique to a particular individual or event. Thus, nomothetic research addresses such questions as whether creative development is enhanced when talented individuals are exposed to models of creativity. In contrast, idiographic research might address an issue such as the reason why van Gogh cut off his ear. Hence, in this sense historiometrics has goals comparable to other methods that psychologists use to study creativity, such as psychometrics.

In line with this focus, historiometric research favors multiple-case investigations. Only by obtaining a large sample of eminent personalities or important events can the researcher ensure that the findings are truly general rather than particular. It is rare for a historiometric inquiry to analyze fewer than a dozen cases, and sometimes the sample sizes may run into the thousands. Indeed, the largest number of cases ever examined in a single historiometric inquiry was 15,618, a very large sample size indeed (Simonton, 1980).

Also consistent with the search for nomothetic results, historiometric research invariably entails quantification. Variables are first quantified from the available archival materials, and then these variables are subjected to statistical analysis. Because the number of variables studied will often be very large, the investigator usually must apply sophisticated multivariate statistics to tease out the

☆ *Change History:* Jan 2019. Dean Simonton updated the text throughout the article.

This article is an update of D.K. Simonton, *Historiometry*, Editor(s): Mark A. Runco, Steven R. Pritzker, *Encyclopedia of Creativity* (Second Edition), Academic Press, 2011, Pages 617–622.

complex interrelationships among the variables. The most commonly used statistics are multiple regression and factor analysis, but occasionally one sees studies using path analysis, latent-variable models, time-series analysis, multidimensional scaling, and hierarchical linear models. Needless to say, given the typical sample sizes and the complexity of the statistical analyses, historiometric studies almost invariably must be executed on a computer.

Comparisons

It is important not to confuse historiometric research with several alternative approaches. To begin with, historiometry differs substantially from psychobiographical and psychohistorical studies of creativity. The latter almost always employ qualitative rather than quantitative methods, and they tend to be idiographic rather than nomothetic in orientation. In addition, psychobiographical and psychohistorical inquiries are very often psychoanalytic in theoretical emphasis. These characteristics are evident in the classic psychobiography of Leonardo da Vinci that was published by Sigmund Freud in 1910. Historiometry, in contrast, is a method designed to test hypotheses that might be drawn from any theoretical framework, psychoanalytic or otherwise. An excellent example is Colin Martindale's 1990 book *The Clockwork Muse*, in which the author tests a formal model of stylistic change that has roots in psychoanalytic theories of creativity.

Another approach is sometimes confused with historiometry is the comparative. Comparative research takes a modest size sample of individuals or events and then tries to discern consistent patterns or regularities. Although the goal is often nomothetic, the method is qualitative. A good illustration is Howard Gardner's 1993 book *Creative Minds*, in which he carefully compares and contrasts the lives of seven eminent individuals. Comparative studies can lead to important insights about creativity and other phenomena but do not share historiometry's capacity for more precise model testing and prediction.

Lastly, historiometry must not be equated with cliometrics (Simonton, 2008). Although the two terms have similar etymologies—both literally mean “history measurement”—cliometrics has become associated with quantitative research in economic history. Here the goal is to test a historical question by applying econometric methods and economic theory to archival data. A classic example is the cliometric research on whether slavery was a profitable business in the antebellum US South. Although important, this issue has no psychological content, nor does it concern creative geniuses.

History

Surprisingly, historiometry actually represents the earliest scientific approach to the study of creativity. In 1835 Adolphe Quételet published a quantitative analysis of eminent English and French playwrights in which he established the relationship between age and creative output. The next important historiometric inquiry was the 1869 book *Hereditary Genius*, in which Francis Galton documented how eminent creativity (and leadership) tends to run in family lineages. Other pioneer historiometric investigations include Alphonse de Candolle's (1883) study of eminent scientists and Havelock's (1904) study of British geniuses.

However, none of these researchers explicitly identified their work as historiometric, for the term had not yet been invented. The word was not coined until the first decade of the 20th century, when Frederick Woods (1909) and (1911), a geneticist, patterned the term after biometrics. Although Woods's own historiometric research focused more on famous leaders than creators, the term was adopted briefly by others. Most notably, Catharine Cox's (1926) study of the *Early Mental Traits of Three Hundred Geniuses* was explicitly labeled a historiometric inquiry. This monumental investigation, which constitutes the second volume of Lewis Terman's (1925–1959) *Genetic Studies of Genius*, provided quantitative assessments of the intelligence and personality of famous creators and leaders.

Cox's work inspired other historiometric studies, but unfortunately both the method and the term virtually disappeared from the research literature on creativity. Beginning in the mid-1970s, Dean Keith Simonton began to revive the technique and the name. At present, historiometry seems to represent a relatively rare but nonetheless acceptable approach to the study of creativity. Indeed, from time to time it has attracted the efforts of eminent psychologists whose primary contributions have employed very different methods. Among these holiday historiometricians are James McKeen Cattell, Raymond B. Cattell, B. F. Skinner, Lewis Terman, and Edward L. Thorndike.

Research

One of the reasons that historiometric research may be here to stay is the tremendous amount of important empirical results it has generated. The great diversity of findings may be grouped into two inclusive categories: those concerning the creative individual and those concerning the creative product.

The Creative Individual

The largest proportion of historiometric studies of creativity examines those individuals who have achieved acclaim for their original contributions to some domain. These studies have tended to focus on the following three topics:

Individual Differences

Even among eminent creators, the cross-sectional variation in creative success is quite substantial. To appreciate the contrast, we need only compare Newton with William Higgins, Descartes with Henri Duroy, Shakespeare with Chatterton, Michelangelo with Hendrick Bloemaert, Beethoven with Anton Reicha—all pairs of individuals who have rubbed elbows in the same historiometric samples. Much of the contrast in differential reputation can be ascribed to differences in creative output. Accordingly, many studies have examined individual differences in lifetime productivity, including the peculiar skewed (or elitist) distribution of that output. Other studies have examined the personality and intellectual factors responsible for the cross-sectional variation in output and eminence. For example, Cox showed how success required a combination of both high intelligence and unusual motivational persistence. She also demonstrated how the distinctive personality profiles of eminent creators vary according to the domain of creative activity.

Life-Span Development

Rather than concentrate on individual differences, many historiometricians have studied how creativity develops and manifests itself across the life span. These developmental inquiries fall naturally into two distinct categories. In the first category are those that look for the early antecedents of adulthood creativity. For instance, researchers have examined the impact of such variables as family pedigree, socioeconomic class, childhood precocity, birth order, orphanhood, role models and mentors, crystallizing experiences, and formal education or special training. [See Birth Order; Enhancement of Creativity; Families and Creativity; Prodigies.]

In the second category are those developmental studies that scrutinize how creativity varies across the course of the career. Most of these studies are concerned with how the rate of output changes with age. The expected age curves tend to vary systematically according to the specific type of creativity. For example, poets and mathematicians tend to produce masterworks at younger ages than do novelists and earth scientists. Other studies have examined the longitudinal relation between total quantity of output and the odds of producing a masterwork. Significantly, a creator's best work tends to appear in those periods of the career in which he or she is the most prolific overall.

Sociocultural Context

Illustrious creators are not randomly distributed across history, nor are they evenly spread across the globe at any one time. On the contrary, creative genius is more prone to appear during "golden ages," less likely during "silver ages," and supremely unlikely during "dark ages." The Golden Age of Greece is a classic example. Such uneven distribution suggests that political, economic, social, and cultural forces may play a major role in the development and manifestation of creative talent. Historiometric investigations have specifically examined such factors as war, political system, ideology, and general intellectual ferment. These studies show that the "spirit of the times," or the *zeitgeist*, claims a crucial part in the origination of creative genius. The *zeitgeist* influences not only the number of eminent creators that appears in a given time and place, but also the particular domains in which creativity is most likely to be displayed. [See *Zeitgeist*.]

The Creative Product

Because the eminence of a creator is very much contingent on the works he or she contributes to posterity, it is natural for historiometricians to investigate the characteristics of these artifacts of the act of creation. Some of this research has examined scientific discoveries and technological inventions. For example, several studies have been published on the multiples phenomenon where two or more scientists independently (and sometimes simultaneously) arrive at the same idea at about the same time. Classic illustrations include the proposal by Charles Darwin and Wallace of the theory of evolution by natural selection and the invention of the calculus by Newton and Leibnitz. Surprisingly, certain distinguishing features of these events—such as their timing and the number of participants—can actually be accurately predicted using mathematical models. [See Creative Products.]

However, most inquiries into the creative product focus on the arts. Many of these studies are specifically devoted to the determination of the factors responsible for aesthetic effectiveness of compositions in literature, music, or the visual arts. For instance, the application of computerized content analysis to classical music has enabled researchers to predict the relative performance frequencies of works in the repertoire. Similar historiometric techniques have had comparable success in the prediction of the differential popularity of literary creations, such as poetry. In addition, several historiometric studies have been concerned with qualitative changes in the nature of the works produced over the course of a career. Of special interest are inquiries into the swan songs of classical composers and the late-period style changes in visual artists. The research shows that toward the very end of a creator's life the very nature of her or his creative output may undergo a dramatic transformation. [See Art and Aesthetics.]

Evaluation

The reason why the behavioral scientists have so many different techniques at their disposal is because no technique is perfect. Each enjoys certain assets, and each suffers from certain liabilities. Historiometry is no exception. It, too, has both advantages and disadvantages. Let us look at the latter before turning to the former.

Disadvantages

Any researcher interested in applying historiometric methods to the study of creativity must often confront one or more of the following four problems:

Causal Inference

Methodologists sometimes distinguish between internal and external validity of a technique. The former criterion concerns the security of the causal inferences the method permits. Laboratory experiments enjoy very high internal validity because the experimenter actively manipulates the independent variables and randomly assigns subjects to experimental and control groups. Historiometric research, in contrast, is inherently correlational in nature. The best the researcher can do is to determine how measured variables are associated. Because other unmeasured factors may contaminate the observed relationships, conclusions about causal influence are invariably insecure. Correlation never can be taken to prove causation. Thus, the internal validity of historiometric work is almost always inferior to that found in the experimental literature. For example, one of the oldest debates in the study of creativity is the relationship between genius and madness. What makes this issue especially irksome is the difficulty of determining which of three distinct possibilities is most likely to hold: (a) a proclivity toward psychopathology might make a positive contribution to creativity; (b) exceptional creative achievement might put exceptional strain on creative individuals, thereby making them more disposed to mental and emotional breakdowns; and (c) neither creativity nor psychopathology may have any direct causal relationship with each other but rather might be the consequence of some other factor or factors (e.g., traumatic or unconventional childhood experiences. [See Mad Genius Controversy.]

Data Quality

Because the historiometrician must rely so much on the historical and biographical record, sometimes the available information leaves much to be desired from a scientific standpoint. For example, when Cox (1926) attempted to calculate IQ scores for historic personalities, she lamentfully discovered that she had to exclude William Shakespeare from her sample. There exists very little data about the Bard's personal life and virtually nothing about his early years. Even when enough pertinent information could be found in the historical record for a particular individual, Cox found that the reliability coefficients for her IQ assessments could vary substantially from genius to genius. Moreover, when she wished to estimate 67 personality traits for her subjects, she was obliged to restrict her sample to the 100 famous people about whom the most data were available.

Substantive Applicability

Closely related is the fact that some important issues in the scientific study of creativity probably cannot be addressed using historiometric methods. For instance, one of the central questions in the creativity literature is the very nature of the creative process. What is the role of intuition or unconscious processes? What is the function of logical analysis? Yet the biographies and published letters of eminent creators do not contain the necessary information in any systematic fashion, and when the records do, they cannot always be trusted as sources of solid data. For example, Samuel Coleridge's description of the creative process underlying the composition of "Kublai Khan" is inconsistent with his own unpublished manuscripts that contain the various drafts of the poem. It is now apparent that he distorted his narrative to render the episode more consistent with romantic notions of the creative process.

Labor Requirements

Perhaps the most prohibitive drawback of historiometric research is the sheer amount of work required to carry out a project. Collection of the raw data may require many trips to the library and special archives, followed by the arduous coding of qualitative information to get the data in quantitative form. Even after the content analytical, historical, and biographical data have been reduced to numbers, the statistical analyses may consume considerable amounts of time. Historiometric data sets often involve numerous variables with highly complex interrelationships that can only be teased out using the most advanced statistical techniques. As a consequence, it is not uncommon for a major historiometric study to require several *thousands* of hours of effort to produce a single journal article. That is a small payoff in comparison to, say, a laboratory experiment in the area of creative problem solving. Naturally, monograph-length investigations may demand even more time and effort. To offer one dramatic example, Frank Sulloway's book *Born to Rebel* represents the culmination of 26 years of intensive data collection and analysis.

Advantages

The forgoing liabilities notwithstanding, often one or more of these problems can be alleviated if not entirely removed in well-conceived historiometric research. First, multivariate statistics and quasi-experimental designs have immensely increased the power of drawing causal inferences from correlational data. One especially potent inferential tool is time-series analysis. Second, data quality problems can often be handled by the introduction of more sophisticated statistical methods, such as latent-variable models. These permit the explicit incorporation of measurement error into the causal model. Third, the substantive applicability of historiometry can often be greatly extended if the investigator exercises care in selecting the optimal research site. For instance, sometimes a researcher may examine famous creators from non-Western civilizations precisely because the biographical and historical information is available regarding a particular set of variables. Fourth, if the investigator plans carefully and compiles a rich

enough database, it is possible to generate more than one publication from a single data collection. For example, once a researcher decides on using a particular sample of Nobel laureates as the basis for the investigation, he or she can gather a great diversity of biographical, historical, and content analytical data that can be used to test a wide variety of hypotheses.

Besides these extenuating circumstances, researchers often have very strong reasons for adopting historiometric methods for a particular investigation. Five assets may be the most important from the standpoint of creativity research.

Criterion Validity

One of the main problems in studying creativity is how to measure the phenomenon. Some researchers may define creativity in terms of scores on a psychometric instrument, whereas others may rely on judges' evaluations of creative products. Although these conventional assessments have much to recommend them, they are also not without conspicuous limitations. For example, a measure cannot be called a "creativity test" without first validating the instrument against some more secure criterion of creativity. Perhaps scores on such tests have absolutely nothing to do with real-life creativity. Historiometric research circumvents this problem by studying those individuals who have made a name for themselves precisely for their creative achievements. If the investigator examines persons like Planck, Sartre, Joyce, Picasso, or Stravinsky, we have no other option but to assume that these individuals exhibit creativity. If we were to deny that attribution, the term *creative* would lose all meaning. Hence, historiometric methods take their point of departure at those individuals who best exemplify the phenomenon under investigation.

Variable Accessibility

There are many important influences on creativity that for both practical and ethical reasons can only be examined using historiometric methods. If the goal is to determine the sociocultural milieu that best contributes to the development of creative development, it is hard to imagine a better method than to scrutinize the historical record with respect to the coming and going of creative genius. For instance, if we want to test the hypothesis that wartime conditions inhibit the expression of creativity, we probably have no other choice than to conduct a time-series analysis comparing the output of creative products against the magnitude of political violence (*See War*). Even if the focus is on creative careers, the assets of historiometrics are paramount. The researcher can examine the emergence and manifestation of creative genius from the moment of conception (e.g., family pedigrees) to the moment of death (e.g., swan songs) and everything in between (e.g., birth order, childhood trauma, role models and mentors, education and special training, and career trajectory). Historiometry is thus truly life-span developmental in scope.

Unobtrusive Measurement

Ever since the advent of the Heisenberg uncertainty principle in quantum theory, physicists have learned that the very act of measuring a phenomenon may interfere with the phenomenon under scrutiny. A similar consequence often may be seen in many standard methods in the behavioral sciences. For example, the very act of studying the creative process in the laboratory may distort the observed behavior to such a degree that it becomes unrepresentative of what would happen under more natural conditions. Similarly, the application of psychometric measurement, surveys, and one-and-one interviews to samples of contemporary creators may produce expectancy effects, "guinea-pig" effects, and other kinds of artificial reactions. Historiometric measurement, in contrast, is totally unobtrusive. The subjects in historiometric inquiries do not know that they are under observation. Indeed, because the subjects are most often deceased, they will never find out the results. Accordingly, the phenomenon of creativity can be investigated without fear of inducing unnatural responses from the subjects of the study.

Cross-Cultural and Transhistorical Invariance

Behavioral scientists seek general laws or principles of behavior that transcend place and time. If an empirical relationship only holds for a particular culture or is merely valid for a single historical period, it cannot have the claim to universality that is the hallmark of all nomothetic science. For example, Newton's law of gravitation holds not only for apples falling from trees in 17th-century England but also for all massive bodies in the universe throughout the history of time. One great asset of historiometric research is that it can sample creators from all civilizations of the world and from every major historical period. Hypotheses tested on such diverse sample have a much higher probability of claiming cross-cultural and transhistorical invariance. For instance, one historiometric investigation of literary creativity showed that poets produce their best works at younger ages than prose writers. Furthermore, this differential was shown to be invariant across historical time and geographical origins. Because the sample consisted of hundreds of literary figures drawn from all the world's major literature from antiquity to the present day, we can have greater confidence that this result is not confined to, say, such 19th-century British authors as Keats, Shelley, and Byron.

Unit Replicability

One of the peculiarities of historiometric research is that the subjects who compose its samples can all claim a permanent and distinct identity. After all, the individuals under scrutiny have made a lasting name for themselves on the basis of their creative contributions to human culture. As a consequence, it is not uncommon for historiometric studies to identify their subjects by name, listing them either in a table or in an appendix. For instance, Cox listed all 301 geniuses whom she studied along with some of the basic information compiled about each, including the estimated IQ scores. Other times the researcher will give sufficient details about the sampling procedures—such as the precise biographical dictionaries used—that any reader can easily determine who the famous personalities under investigation were. In any case, because the subjects are identified or identifiable, subsequent investigators can study exactly the same individuals, adding new variables and altering the statistical analyses

performed. For example, the eminent persons in the Cox study have been re-examined in several follow-up inquiries published over an 80-year period.

This asset of unit replicability allows the historiometrician to improve on previous results in a manner that can accelerate the accumulation of scientific knowledge. Most alternative methods lack this feature. A laboratory experiment can always be replicated in terms of method, but not in terms of subjects. As a consequence, when experiments fail to replicate a previously published finding, it is uncertain whether the contrast may be ascribed to the change of participants in the study. In contrast, when a historiometrician scrutinizes the exact same subjects as analyzed in a previous study and fails to obtain identical results, the cause of the discrepancy can be more easily isolated.

Conclusion

Because historiometry has already been around in the behavioral sciences for more than 180 years, its use will likely continue in the future. The technique has already made considerable contributions to our understanding of creativity in its most historic manifestations. Moreover, the method enjoys many methodological advantages over other research strategies. Above all, it is the technique of choice for anyone who wants to test nomothetic hypotheses about history-making creativity. No alternative method features the same inferential rigor and quantitative precision. Moreover, despite various methodological disadvantages, many of these drawbacks are becoming ever less critical. Certainly statistics for analyzing correlational data are becoming increasingly sophisticated, permitting ever more powerful causal inferences. Even more important, the quality of the data about historic creators is becoming increasingly better with time. After all, creativity is not dead in the world, and each generation will usually produce a new crop of eminent creators that can serve as subjects in future historiometric research. Furthermore, there will probably be more and better information about these forthcoming creative individuals than holds for those born in earlier historical periods. Indeed, historiometric research has actually demonstrated that the reliability coefficients for many variables have increased over time. Finally, with the advent of the internet, the available information has not only become more detailed but also more accessible. The investigator can often download all or most of the data for a particular historiometric inquiry directly from an internet database.

In a sense, the situation for the historiometrician is very similar to that of the astronomer centuries earlier. The first astronomical measurements were rather too imprecise to support anything more than the crudest planetary theories. But as observations became more precise, the archival records collected by astronomers began to encourage the development of increasingly sophisticated theories. I predict that historiometry will enjoy the same historical trend with respect to its own phenomena. In fact, in some respects it has already done so. As mentioned in the section on the method's history, the first historiometric study ever published dates back to 1835. That investigation concerned the relationship between age and creative productivity. Since that pioneering inquiry, many investigators have scrutinized the same question using ever more precise measurement and statistical analysis. Now the cumulative body of evidence on this question has reached the point that researchers have begun to propose mathematical models that provide rather precise predictions about how creative output changes across the life span. Hence, in this substantive domain at least, historiometrics can indeed provide the foundation for scientific progress in our comprehension of creativity. The same progress should be seen with respect to other topics that attract historiometric inquiry.

Introduction

Like creativity, humor makes life worth living. Both play central roles in our mental and social lives, and both appear to be uniquely human (or nearly so). As topics of scientific inquiry, they also have much in common – conceptually, methodologically, and in proposed explanatory frameworks. Both humor and creativity involve a person producing something (such as an artwork, a scientific theory, or a joke) that is regarded by some audience as novel, unexpected, and valuable (or funny). Within the context of humor research, the topic of creativity is most directly relevant to humor production: how a person generates a new joke, witticism, observation, or other creative product that is found funny by others. Additional facets of the psychology of creativity – including underlying cognitive mechanisms, issues of reliability and validity of measurement, personality, and evolutionary origins – are also relevant.

This entry will outline some basic features of the psychological study of humor and describe conceptual links between humor and creativity, encompassing both classic and contemporary lines of scholarship. Then work in a few specific research areas relevant to the nexus of creativity and humor will be explored. These include their psychometric relations, the influence of personality, the association between humor and the “a-ha!” phenomenon of insight, the relation of humor production to allied constructs like humor comprehension and appreciation, and an overview of recent research attributing the evolutionary emergence of humor and creative abilities to Darwinian sexual selection. In each case, possible future research directions are outlined, which would further develop these potentially fruitful but still under-studied and under-integrated topics.

The Psychology of Humor

The psychology of humor is a specialized yet rich area of research. It draws upon virtually all the main methodologies and subdisciplines within psychology, including psychodynamic, cognitive, developmental, social, personality, psychobiological, health, and evolutionary perspectives. Humor is a human universal. It involves a suite of cognitive-perceptual and emotional processes deployed in particular social contexts and supported by biological markers like smiling and laughter. Its expressions include formalized jokes, spontaneous conversational humor, and unintentional instances of humor. Humor also pervades creative domains like cartoons, literature, theater, films, and even instrumental music – as in Mozart's *A Musical Joke* (K. 522), a matchless parody of compositional and performative incompetence. Humor serves varied purposes, many of which are social in nature. These include interpersonal bonding via the positive emotion of mirth, direct and indirect communication, signaling of group membership, social influence, conflict de-escalation and tension reduction, and displays of status or genetic fitness.

Psychological theories of humor address many questions. These include the various functions of humor, the cognitive processes required to 'get' a joke, like creating and then resolving incongruities or engaging in cognitive reversals, humor's developmental stages, and different styles of humor, including affiliative, aggressive, self-enhancing, and self-defeating.

In sum, the psychology of humor encompasses a range of topics, which are comparable in scope and complexity to issues raised in the psychological study of creativity: indeed, there are many fertile links between the two areas.

Links Between Creativity and Humor

Earlier Views

Despite close conceptual links between humor and creativity, historically there has been a pragmatic separation between the two fields. Most creativity researchers do not study humor, and vice-versa; those who do research in both areas tend to be mainly associated with only one; few researchers are equally conversant with both topics, and those that are often have primary roots in yet a third domain. Emblematic of this dissociation, [Runco's \(2007\)](#) comprehensive textbook on creativity contains only a single page reference to humor; [Martin's \(2006\)](#) equally comprehensive textbook on humor has only seven page references to creativity (Each book consists of over 400 pages.) And just as scholars of creativity often publish in specialized journals on their topic, humor also has its flagship *HUMOR: International Journal of Humor Research* (<https://www.degruyter.com/view/j/humr>).

Despite this parallel play, over the years a trickle of research has attempted to integrate the two areas. Indeed, psychological researchers have long treated creativity and humor as closely related constructs. Mainstream conceptions of both humor and creativity involve unpredictability, novelty, incongruity, and surprise, and both require playfulness and risk taking. Humor and creativity each show pronounced individual differences and both are regarded as desirable personal characteristics. A sense of humor has long been regarded as a characteristic of creative individuals. At times, humor has been regarded as a subset of creativity or as a separate but partially overlapping domain. Understanding the psychometric relations between aspects of humor and creativity raises questions that mutually inform both constructs, but a more detailed discussion of this topic will be reserved for later.

Some theoretical treatments of humor show striking similarities to venerable theories of creativity. For instance, [Apter's \(1982\)](#) 'reversal' theory of humor emphasizes cognitive processes of a 'play' orientation to the world and one's actions in it. In outlining his theory, Apter described a cognitive process in which two contradictory ideas are simultaneously held in mind, which closely resembles the 'bisociation' view of creativity described by [Koestler \(1964\)](#). Similarly, a common characterization of humor as exploiting loose but meaningful associations between concepts echoes the classic notion of remote associations between concepts as ideational grist for the creativity mill. Further, some measures of creative ability or personality include assessments of humor among the survey items.

Finally, it is worth noting that one early psychological theory of humor was proposed by [Daniel Berlyne \(1972\)](#), a major figure in the history of psychological aesthetics (and by extension, creativity). Berlyne proposed that both aesthetic creative products and humorous productions are characterized by so-called collative variables, such as novelty, surprise, ambiguity, and incongruity, which naturally attract our attention and boost arousal. These same variables (and their underlying arousal-increasing mechanisms) are thought to play a central role in the creation and stylistic evolution of creative works in virtually all aesthetic domains. While art and humor share such attributes, Berlyne also suggested that humor is distinguished from other aesthetic experiences by its typically brief timescale over which changes in arousal occur, the presence of cues that preclude seriousness, and the extreme bizarreness of the collative variables involved in humor.

Contemporary Views

The 'classic' work reviewed so far is typically multiple decades old and mainly originated within humor (rather than creativity) studies. However, this line of inquiry flows naturally into contemporary conceptions and frameworks of mainstream creativity research. Indeed, there has been no shortage of challenging scientific questions (and opportunities for synergy) on these fronts, since both humor and creativity are complex, multi-faceted, and interdisciplinary phenomena, presenting researchers with a host of conceptual and methodological hurdles. In attempting to meet such challenges, creativity researchers have converged upon several guiding frameworks, which can easily be made relevant to the study of humor. These include the so-called six P's of creativity, the four levels of creative achievement, the notion of idea generation as arising from the combination of different concepts, as well as agreed-upon methods for assessing creativity. Each is now described in turn.

The Six P's of Creativity

One useful organizing theme in creativity research involves the so-called six P's of creativity: the creative person, the creative product, the creative process, the creative place, creativity as persuasion, and creative potential ([Kozbelt et al., 2010](#)). Different lines of research and creativity theories pursue varied subsets of these P's. Depending on a researcher's questions and approach, any of the P's can also be made relevant to the study of humor. For instance, researchers interested in different styles of humor or their relation to well-established personality dimensions will focus on the creative person. Those interested in establishing reliable and valid measurement of humor will highlight the creative product. Cognitive theorists interested in understanding the mental

processes associated with the genesis of a humorous thought will emphasize the creative process. More applied researchers interested in describing or designing environments to optimize humor or creative productivity will prioritize understanding the creative place. Sociologically-minded scholars interested in how new forms of humor arise and take root, or in how humor can be used to facilitate social change, will stress creativity as persuasion. Education researchers interested in identifying untapped creative or humor ability will emphasize creative potential.

Four Levels of Creative Achievement

Another useful framework for understanding creativity concerns the level of a person's creative achievement. A current theory posits four such levels, which progressively build on each other: mini-c, little-c, pro-c, and Big-C creativity ([Kaufman and Beghetto, 2009](#)). As with the six P's, each of these four levels is directly applicable to the study of humor. A mini-c creative episode might involve an individual's brief, private realization about some everyday event that is both humorous and personally novel, which provides a moment of mirth. A little-c extension could involve that person sharing the realization with a friend, having elaborated the basic idea somewhat and giving it a pithy delivery in conversation. If that individual was a professional comedy writer or stand-up comedian, and then used that insight as part of a script or act, this would constitute a pro-c level of achievement. Finally, if that observation became part of the broader culture and was passed down as a comedy classic, it would have become an instance of Big-C creativity. Humorous pro-c and Big-C creative accomplishments in popular culture are most closely associated with superstar stand-up comedians, as well as well-known comic writers, actors, and actresses (See *Comedians*). In the fine arts, Big-C-level humor may be associated with luminaries like Aristophanes, Rabelais, and Twain in literature, with visual artists like Hogarth, Klee, and Steinberg, and classical composers like Haydn, Shostakovich, and Schickele. This roster of eminent historical creators represents another conceptual link between the study of humor and creativity, since the works of such persons are often the focus of Big-C creativity research.

Idea Generation as Conceptual Combination

Another overarching principle in the contemporary study of creativity is a heuristic division of the creative process into two fundamental regimes of thought: one in which ideas are generated and another in which those ideas are elaborated into finished creative products. In many current creativity theories, the process of generating new ideas is the primary engine of creativity and consists simply of combining two or more previously unassociated ideas. These novel conceptual combinations provide the raw material for creative thought, even though most potential combinations are sterile or meaningless. However, the process of combining existing ideas or concepts skirts the thorny issue of where new ideas come from; moreover, theories which assume that such a combinatorial process undergirds creative productivity have shown remarkable accuracy in accounting for phenomena as diverse as patterns of lifespan creative productivity and trans-historical style changes in the arts.

This view of idea generation as a form of conceptual combination is another notable link between established theories of creativity and humor. This is particularly true of incongruity theories ([Suls, 1972](#)) and reversal theories ([Apter, 1982](#)) of humor, in which two contradictory ideas or concepts regarding the same object are held in mind at the same time. When a person engages this process in a playful way, the combinations or synergies are thought to be enjoyable and to increase arousal, as in many situations involving aesthetic appreciation. Despite broad agreement on the importance of conceptual combination processes in humor and creativity more generally, many questions remain unanswered. For example, does punch-line humor involve the simultaneous recognition of incongruous or contradictory viewpoints, or their resolution?

Assessment Issues and Methods

Besides the theoretical links between creativity and humor noted earlier, the two domains also share methodological concerns. Since both creativity and humor can be considered forms of ill-defined problem solving, there is no pre-set correct answer; rather, there is a range of better versus worse solutions. In that case, researchers must have some way of determining which outcomes are more creative or funnier. In creativity research, new ideas or productions are usually assessed by qualified outside raters using survey instruments, along the lines of the Consensual Assessment Technique. Similarly, the quality of humor production is often assessed by having individuals generate punch lines or captions to photographs or cartoons, which are likewise judged for funniness or other criteria by outside raters. Humor quality is also sometimes assessed by mirth response, which involves spontaneous reactive indications of a person finding something funny, like smiling. In both domains, ratings need to achieve adequate inter-judge reliability for the measurement to be useful in distinguishing more creative or humorous instances from those that are less creative or humorous. Ideally, the production task also reflects the way in which such processes play out in the real world, which would yield a valid measure of the construct in question. Because value judgments of creativity and humor are inherently subjective, inter-judge agreement in this line of research is lower than in some other areas of research, where objective criteria of success can be better defined. Despite this, adequate levels of reliability are often achieved in laboratory research studies. This allows the study of creativity and humor to be placed on a reasonably firm empirical footing.

Despite mixed results on aspects of humor and creativity, methodologically exemplary modern studies, like that of [Nusbaum et al. \(2016\)](#), have continued to amass empirical evidence showing fundamental links between the two topics, finding – in this case – positive correlations across a range of humor production tasks, including cartoon-captioning, joke-completion, and

generating definitions for novel noun-noun pairs. These positive correlations suggest that they measured the same underlying humor production ability and that humor ability has much in common with other forms of verbal creativity.

Finally, beyond correlation approaches, and again consistent with links between humor and creativity, several experimental or quasi-experimental laboratory studies suggest that creativity can be enhanced through exposure to humor, training in improvisational comedy, framing a task as humorous, or simple instructions to use humor in completing a creativity task.

Humor Production and Creativity: Issues in Current Research

The previous section detailed some general links between creativity and humor. In this section, several areas of special importance in current research are described, with an eye to identifying promising future directions.

Psychometric Relations

As just noted, assessing either humor or creativity by itself raises significant methodological issues. This is compounded when the relations between the two are examined. Indeed, much research on productive aspects of humor is plagued with methodological shortcomings, sometimes failing to meet standard psychometric criteria of reliability and validity.

Despite such qualms, over the years, numerous research studies have examined the statistical relations between aspects of humor and creativity. For instance, [Feingold and Mazzella \(1991\)](#) found a positive correlation between humor reasoning and performance on the Remote Associates Test, often taken as a measure of creative thought. Other researchers used varied humor production tasks (like generating funny captions to cartoons or photos, or funny campaign slogans), and often found moderate positive associations with various measures of creativity (like Remote Associates or Alternative Uses tests). A meta-analysis of such studies by [O'Quin and Derks \(1997\)](#) found a moderate positive relationship between measures of sense of humor and measures of creative abilities (average correlation = 0.34). Thus, persons with a greater sense of humor also tend to be creative in other domains. Such a relation does not, of course, identify a causal arrow, and indeed, O'Quin and Derks noted that confounding factors like general intelligence could underlie this relation. Other explanations for this association include cognitive processes activating multiple schemas to resolve incongruities in humorous and creative situations or positive affect associated with humor reducing tension and rigidity in thinking and boosting creativity.

Initial forays into the assessment of humor, creativity, and their relations suggest sensible empirical linkages between these conceptually similar constructs, as well as related abilities like intelligence ([Kaufman et al., 2008](#)). Future research would benefit not only from greater conceptual clarity making distinctions between sub-types of humor and creativity, but also by methodological improvements like more diverse samples and tasks, deemphasizing self-report measures in favor of individual-difference performance measures, and treating data in more up-to-date and sophisticated ways – for instance, in using latent-variable and hierarchical regression models.

The Influence of Personality

Much has been written about the creative personality. Research on the standard Big Five personality dimensions and various aspects of creativity has consistently revealed that the dimension of Openness to Experience is much the strongest predictor of creativity; of the remaining dimensions, only Extraversion also sometimes shows a positive association with creativity.

Research on humor and personality is sparser, but unsurprisingly, Openness to Experience and Extraversion are again most frequently invoked as likely correlates. Several studies found reliable positive relations between Openness to Experience and performance on humor production tasks. As with creativity, results linking humor and Extraversion are somewhat weaker and more controversial. Continued research linking personality dimensions to more nuanced aspects of creativity in different domains or different styles of humor would likely represent a fertile step forward on these issues.

Humor and Insight

A prominent aspect of the study of creativity is the phenomenon of insight: an “A-ha!” moment in which a person has a sudden realization of the answer to a problem that they were previous unable to solve. Insight has been explicitly linked to humor – particularly humor comprehension – in that the same kind of mental restructuring thought to occur in creative insights can also explain how people quickly revise a concept in the course of getting a joke. Research on humor comprehension has yielded support for this connection. For instance, when participants are shown cartoons accompanied by either a correct or incorrect interpretation and are asked to say whether a given interpretation is correct or not, right answers are made more quickly than wrong answers, correct interpretations are identified more quickly and those cartoons are rated as funnier than cartoons accompanied by incorrect interpretations ([Kozbelt and Nishioka, 2010](#)).

But humor comprehension is not the only arena for insight-like processes. Given the ability of some people to produce rapid-fire repartee and wit, both in everyday conversation and domains like improv comedy (see Improvisation), something resembling insight seems likely to undergird humor production as well as humor comprehension. Little direct evidence has thus far emerged

on this point. However, some research on humor production has found indirect support for this view; for instance, when participants generate many potentially humorous ideas, many of the funniest instances emerge rather early in the session, which could result from quick associations or from pattern-matching to familiar kinds of jokes in a person's long-term memory. A stronger link between insight and humor production could emerge from studies using a finer-grained examination of the time course of one (rather than many) humorous idea. Alternatively, effective humor production may simply rely less on brief, insight-like mental processes than on more protracted elaborative, metacognitive, or self-monitoring processes – perhaps especially in well-rehearsed stand-up performances or in comedy screenplays, where small changes in wording or timing can make a big difference in perceived humor quality. This set of issues awaits future research.

Humor Production, Humor Comprehension, and Humor Appreciation

Whether or not humor production stems mainly from processes that are brief or protracted, a fruitful approach to understanding humor is to embrace it as an individual-difference ability variable. Clearly, some people are more adept at producing humor than others. Are there other aspects of humor on which such persons show systematic advantages? The clearest evidence bearing on this question concerns the relation between humor production and humor comprehension. It is hard to consistently produce effective humor if one cannot understand it.

Several research studies have shown positive associations between humor production and comprehension, even when comprehension is measured using tasks that have no productive component. Interestingly, humor production ability is usually found not to be correlated with humor appreciation – that is, the subjective experience of finding something amusing (Kaufman et al., 2008). High-quality humor producers may simply have high standards that are unlikely to yield a high humor appreciation score on most laboratory tasks. Notably, available evidence also suggests that humor comprehension is positively correlated with humor appreciation as well as production, despite the observed weak relations between appreciation and production (Kaufman et al., 2008). Refining the relations between these constructs is another avenue for future research.

The Evolutionary Origins of Humor and Creativity

One of the most innovative and contentious aspects of recent humor research involves the question of the origin of the human capacity for humor (as well as for creativity, intelligence, and artistry, broadly defined). How did these capacities emerge? There are several plausible answers. For instance, the ubiquity of humor and laughter among humans might implicate the mechanism of Darwinian natural selection – although this claim yields little information about the particular selection pressures that may have favored humor's evolutionary emergence. Another explanation concerns the capacity for humor to facilitate social bonding, including intimate inter-personal relationships – however, this explanation typically entails a form of group selection, a highly controversial assertion.

Another possibility is Darwinian sexual selection. Unlike natural selection, which focuses on inter-species competition, sexual selection is concerned with intra-species competition. Since females generally must make greater investments in parenting compared to males (and are thus more limited in the number of offspring they can produce), they should be more selective than males in choosing mates, to maximize the genetic quality of their children. Males must thus compete against each other to display indicators of genetic fitness that females will find attractive. In this view, throughout human evolution, an ongoing sexual selection dynamic resulted in complex psychological adaptations like humor, creativity, and intelligence – all of which can be construed as meaningful individual-difference abilities. Indeed, if such differences are stable and have some genetic foundation, this provides the requisite raw material for evolutionary processes to work on.

High-quality humor production has often been regarded as an ability. This individual-differences approach has been adopted by evolutionary social psychologist Geoffrey Miller (2000) (Geher and Miller, 2008), who is the leading contemporary proponent of Darwinian sexual selection applied to higher-level cognition, including creativity, humor, and intelligence. In this view, humor functions as a reliable and valid indicator of genetic fitness, since the ability to produce high-quality humor is difficult and cannot be faked. As the same is true of creativity and intelligence, the sexual selection view implies that all these abilities should be positively inter-correlated, since they all partake of general underlying genetic fitness that confers an aura of “sexiness” on males possessing these characteristics. Indeed, having a good sense of humor is one of the most desired human traits, both socially and sexually. Persons with a good sense of humor are perceived as more friendly, interesting, pleasant, intelligent, emotionally stable, and creative. Using humor also elicits feelings of closeness among strangers and is attractive to potential mates.

Psychometric research has corroborated many of the predictions of sexual selection theory, including positive correlations between humor production, humor comprehension, creativity, and intelligence, as well as sex differences in humor production, with males generally outperforming females in controlled laboratory settings (Greengross and Miller, 2011). Professional standup comedians likewise outperform controls on measures of verbal intelligence, humor production ability, and on each of four well-established styles of humor (Greengross et al., 2012). In addition, research suggests that females prefer males who are adept at producing humor, while males prefer females who are more appreciative of humor (Bressler et al., 2006).

Other lines of research have provided additional converging evidence in support of sexual selection theory. For instance, when females at peak fertility in their monthly cycle are asked to choose between potential mates, the relative desirability of poor but creative men increases; however, this effect is specific to short-term mating (Haselton and Miller, 2006). Miller and Caruthers (2003) found similar short-term-specific effects of increased female fertility regarding females' perceptions of the attractiveness

of men with high humor-production ability. Moreover, in that study, men described as having higher humor production ability were also rated significantly more socially sensitive, adaptable, extroverted, exciting, happy, and able to play well with kids, as well as more intelligent, kind, tall, healthy, masculine, and muscular.

Predictions of such results are unique to a sexual selection-based explanation for the evolutionary origin of humor, compared to other accounts. However, this trait-indicator sexual selection model of humor and creativity is not universally accepted, and several alternative models have been proposed. These include humor as a way of signaling shared knowledge and compatibility, humor as an interest-indicator that allows individuals to test the reciprocity of romantic interest, and humor as a way to signal advantageous parental qualities, such as warmth and prosociality. Despite – or because of – this lively debate, it seems likely that sexual selection will remain an important theoretical framework informing the study of various aspects of humor as well as creativity more generally.

Conclusion

The preceding examples illustrate the range and depth of links between humor and creativity that have been revealed by psychological investigations. Historically, research on these two topics has run in parallel, with only minor overlap and attempts at synthesis – though recent research suggests this may be changing. At their best, treatments of humor and creativity are mutually informative and supporting, broadening and deepening our understanding of human psychology and culture. Moreover, besides the basic scientific benefits of such a synthesis, synergy between the two would also work toward redressing the historic reality of both topics being ‘orphans’ within psychology. Humor and creativity are topics of great popular interest and importance, remain methodologically stimulating for researchers, and have longstanding and copious research literatures. Despite all this, arguably neither area of scholarship is typically given comprehensive (or even adequate) coverage in introductory textbooks and many prominent journals. Humor researchers and creativity researchers are thus allies in the struggle for recognition, as well as the scientific struggle to learn about their respective (and overlapping) research areas – both perennially fascinating domains of human activity.

Introduction

The word “hyperspace” refers to a realm with more than three dimensions. Merriam-Webster added another definition in reference to the popular culture: “a fictional space in which extraordinary events happen.” Creativity is about being and doing extraordinary, but the pathway to the extraordinary, which is the creative process, is probably the least known aspect of creativity. The creative personality is, for example, much more often described in the literature. Yet an authentic explanation for creative achievement must include the underlying process. Without a description of the underlying process, theories of creativity lack explanatory power.

Hyperspace is a concept that [Acar and Runco \(2015\)](#) borrowed in their theory of the creative process. It extends the theory of divergent thinking and allows empirical testing. The term hyperspace was first applied to the creative process in the following:

Divergent thinking can take ideation in all directions. Depictions probably are inaccurate because they are two-dimensional, in which case ideation can only move along the abscissa and ordinate. Ideation can go anywhere, in any of the 360 degrees. This is still a simplification; surely for truly creative thought, three dimensions would be necessary. In fact, given the possibilities of the human mind, what statisticians and science fiction aficionados sometimes call *hyperspace* (with dimensions more numerous than three) ... Each of these [dimensions] implies a unique and perhaps orthogonal dimension for ideation

[Runco 2010](#), p. 19.

This entry explores the philosophical and conceptual foundations of the concept and revisits relevant theories of creative personality. Then it summarizes the empirically tested model of hyperspace categories.

Philosophical and Conceptual Bases

Hyperspace could be visualized as a set of multidimensional continua where each continuum consisting of polar opposites. The idea of opposites has long intrigued philosophers who in many ways influenced modern day psychology. Socrates believed things emerge from their opposites, for example, and the term “dialectics” refers to the method of developing philosophical arguments drawing from contradictory opinions from two opposing sides. The refinement of philosophical arguments may require such an oscillation from one pole to the other. Hegel further delineated this idea with *dialectical materialism* which moves from thesis to antithesis to synthesis. The generation of superior forms of thinking, the synthesis, depends on a thesis and its (opposite) antithesis.

Theories of and research on creativity in modern day psychology are rich with complementary polarities. Even the definition of creativity seems to be having some polarity, at least in the findings of [Runco and Charles \(1993\)](#) that there was inverse relationship between originality and appropriateness in ratings of creative ideas. Divergent and convergent thinking also implies a polarity, and both are involved in successful creative outcomes. Bruner’s “effective surprise” fits here as well: The novelty required for creativity is associated with a feeling of surprise because of the fit or effectiveness. Basadur’s ideation-evaluation cycles is similar for it describes a ratio of ideation-to-evaluation that can predict creative work. Campbell’s model of blind or wide variation and selective retention is another polarity that represents inductive, generative, and branching out nature of creative process followed by elimination and selection. These may sound antithetical but they are both involved in creative efforts. More recently Allen and Thomas distinguished Type 1 from Type 2 thinking, with automatic and fast thinking (Type 1) separated from effortful and logical thinking (Type 2). Another recent theoretical distinction is the dual pathway theory that views successful creative process as involving cognitive flexibility and cognitive persistence. According to this theory, creativity benefits from generation of a variety of categories and clusters as

a result of flexible cognition as well as exploiting each cluster to the fullest, which is facilitated by persistence. An especially intriguing and relevant theory is that of *Janusian thinking*, which is defined as the ability to simultaneously see, imagine, or utilize two contradictory or opposite thoughts, ideas, solutions (see Janusian, Homospatial and Sep-Con Articulation Processes).

Some relevant polarities are not entirely cognitive. Kirton's Adaptation-Innovation approach, for instance, reflects a polarity with two *styles* of creativity. The adaptive style is indicated by efforts at being precise, methodical, orderly, and favoring incremental change. On the other end of the continuum is the innovative style, which is more chaotic, non-linear, disruptive, and prefers radical change. Kirton's distinction seems to be aligned with Hitt's distinction of original thinking versus logical. Hitt called this "two-factor theory of creativity." Long before this work, creativity research borrowed *primary* versus *secondary process* thinking from psychoanalysis.

There is also a view that the creativity resulting from polar opposites is not simply a cognitive skill and process but is more realistically viewed as a reflection of personality (see Paradoxical Creativity). The next section discusses these theories of the creative personality.

Theories of Creative Personality

The creative personality is typically described as independent, autonomous, non-conformist, unconventional, challenging of authority and the status quo, open to change and experiences, flexible, and curious. Creative people tend to exhibit such traits more often than others, but they do not do so under all conditions. There is variation. Barron (1963), for example, described the creative personality with such polarities: "The creative person may be more primitive and more cultivated, more destructive and more constructive, occasionally crazier and yet adamantly saner, than the average person" (p. 234). May (1975) pointed to rigidity vs spontaneity as another polarity, and Maslow (1971) referred to the management of dichotomies, drawing from psychoanalysis and including the conscious vs unconscious and primary vs secondary processes.

Some scholars have listed the common opposites of creative individuals. Torrance and Hall (1980) listed masculinity versus femininity, conformity versus nonconformity, independence versus dependence, serious versus playful, timid versus bold, certain versus uncertain, and receptive versus self-acting. Such a view of creative personality became particularly popular with Csikszentmihalyi (1996) who coined the label the "complex personality." He described creative people as a) having high energy while also being quiet and taking rests frequently, b) smart but naïve, c) playful and yet disciplined and responsible, d) resorting to both imagination and fantasy while staying connected with reality, e) extroverted and introverted simultaneously, f) humble but proud, g) masculine and feminine, h) traditional and conservative while rebellious and iconoclastic, i) objective but passionate, and j) experiencing suffering and pain as well as joy. Csikszentmihalyi argued that one pole helps with "novelty" while the opposite is useful for "acceptance." Truly creative people can use both and, as a result, often become famous for their creative accomplishments.

Csikszentmihalyi (1996) acknowledged that this list is somewhat arbitrary and there may be other dimensions to add. In fact, in a later study Gute et al. (2016) mentioned an agency-communion dimension. This was suggested by their qualitative analysis of Jazz Pianist and Composer Oscar Peterson's creative personality, which also included introversion and extraversion. They argued that classic measures of personality (e.g., the Big-5) fail to identify polarities. Oscar Peterson was both an introvert and extravert. He was an introvert to differentiate himself from others, making him more unique in his domain and allowing him private listening, solitude, and introspection. Once inspired his more natural extraverted side would emerge to integrate his work to the larger world of music through public performance. This cycle of differentiation–integration is a consequence of a pursuit of flow-seeking nature of people with a complex personality.

An early but more structured formulation of complex personality of creativity came from W. Ed McMullan's (1976) work. McMullan's conceptualization emerged from a review of studies that attempted to identify traits that distinguish highly creative individuals from others. Those studies provided contradictory adjectives describing creative individuals. McMullan concluded "the creative person may more closely resemble two thinkers in tandem than one fully integrated being" (p. 266). Because of this nature of creative individuals, he called them "paradoxical personages."

Drawing from May (1975) and Maslow (1971), McMullan also viewed creativity as a polarity between flexibility and persistence. Significantly, these two terms are the exact same terms later used in the *dual pathway* theory of creativity. McMullan argued that flexibility provides freedom, which is critical for creativity, whereas persistence leads to the refinement and feasibility of an idea or solution. He viewed "flexible persistence" as a central trait of creative individuals, which unfolds to eight components: 1) delayed closure, 2) converging divergence, 3) mindless perception, 4) constructive discontent, 5) detached involvement, 6) disinterested selfishness, 7) confident humility, 8) relaxed attention. *Delayed closure* describes creative judgment where the creator keeps an open-mind and prefers complexity but must eventually reach a conclusion or finalize the process with some sort of closure. *Converging divergence* reflects the reasoning process that incorporates de Bono's lateral and vertical thinking, or divergent and convergent thinking, where the former brings novelty and the latter feasibility. *Mindless perception* describes the process in which a creative individual loses oneself in the present through an experience of self-transcendence (see "Flow"), but then brings the experience to consciousness through deliberate and controlled thinking processes. *Constructive discontent* is related to the attitude toward the outcome describing creative individuals' inclination to use positive and affirmative attitudes toward novelty while taking a disruptive attitude against established norms and structured. *Detached involvement* portrays an emotional state of creative individuals which indicates deep immersion in the process of creative activity but can also provide objectivity about the final outcome. *Disinterested selfishness* refers to the motivation of

creative individuals who are both self-centered and in service of greater good for all. Creative individuals' self-concepts are also paradoxical in that they blend humility with confidence. *Confident humility* represents the feelings of self-sufficiency to solve complex problems and accomplish great things accompanied by the feelings of humility in the face of greatness of the external world and smallness and ignorance against it. The last dimension is *relaxed attention* describes creative individuals as on the task with great deal of energy without irrelevant tension.

McMullan connected flexibility to a humble self-concept, disinterested motivation, discontented attitude, mindless perception, divergent thinking, relaxation, delay in closure, and emotional involvement. Persistence was connected to confidence, selfish motivation, constructive attitude, conscious processes, convergent thinking, attention, systematic closure, and emotional detachment. These things reflecting flexibility are more involved in idea formulation whereas persistence allows idea elaboration.

Polarity in Practice

Polarities are useful to recognize in practice. Johnson (1992) viewed polarity management as a critical strategy for "dilemma-solving" in organizations. According to this model, most challenges facing people are not problems where there is a goal but also an obstacle, but dilemmas, and failure to recognize the distinction between the two creates new problems while solving one. According to Johnson, life is full of polarities such as individual versus group, cost versus quality, innovation versus standardization, and individual creativity versus group cohesion. Emphasizing individual creativity may lead a person or group to further encourage individual work, which after a while, may undermine unity, cohesion, collaboration, and lead to a destructive competition. Once this is recognized, the individual or group may find a balancing, with group cohesion harvesting some of its advantages and leading to a stronger preference for group cohesion. There could be more social loafing, loss of individual risk-taking, and lack of personal initiative. Individuals or organizations should be able to recognize the polarities and should steer appropriately when needed.

Puccio (2017) extend this principle to creativity, which he viewed as the antithesis of conformity. He argued that creativity alone does not explain human civilization. Creativity is accompanied by conformity and their co-existence help advance the society. This argument is not far from the idea of personal *discretion* to be creative (see "Personal Creativity" in this volume). Success of a creative activity is most effective when it is deliberate, and people should know when to be creative and when to delay it.

Polarity management takes a value-neutral perspective between the two extremes. This is different than the more common "either-or" thinking leading people to favor and adopt one of the two options over the other. Again, drawing from philosophy, Dewey promoted "both/and" thinking because better solutions lie between the two extremes and in their synthesis. Reflecting the spirit of this trend, recent literature pointed to the positive role of routines and conformity, which used to be perceived as the enemies of creativity in some literature. Miron-Spektor and colleagues (2011) tested if integration of contradictions improves creativity. They found that paradoxes were more appealing to creative individuals and paradoxical structures lead to tension, which in turn motivates people to integrate the contradictions. Consequently, creativity increases with the use of paradoxes and integration of contradictions.

This review described how contradictions, polarities, and the hyperspace containing them is related to creativity. Another area where polarities and the complex personality must be recognized is that of creativity assessment. The next section will discuss an application of polarities to divergent thinking, which is a popular method for the assessment of creative potential.

Literal Divergent Thinking

Acar and Runco (2015) integrated polarity perspective into divergent thinking with special focus on its very definition. Divergent thinking is defined as thinking in many different directions (see "Divergent Thinking"). Not one or two, but in many different directions. The word "diverge" implies ideas branching out from a single point, question, problem, or challenge but assessment of divergence was not really assessed. Acar and Runco used above summarized theories of personality and applied it to the evaluation of divergent thinking tasks. This approach is notably different than the traditional approach scoring responses to divergent thinking for fluency, flexibility, originality, and sometimes elaboration. Those indices do not really reveal pathways or processes to creative solutions, but rather focus on the outcomes of ideational process. The idea behind the literal divergent thinking is to capture directions followed in the ideational processes. If ideas diverge from a single point to multiple directions, the way branch out may be captured and those who use more directions would be performing higher as they literally think in a divergent way. The model involves multiple dimensions with each dimension with two polar opposites. Acar and Runco (2015) revisited the theories of creative personality and attempted to build a model of *hyperspace* involving multiple dimensions where each dimension is formed by two opposites.

Hyperspace Categories in Divergent Thinking

It is not difficult to find polarities with relevance to creative thinking and the creative personality. Some of the polarities mentioned above may be conceptually and theoretically meaningful but not be operational and may not be captured empirically. Acar and

Runco (2015) identifies polarities that are both theoretically and conceptually relevant and could be captured as objectively as possible. Here is their list, with 11 dimensions with thus 22 polarities:

1. Originality vs. conventionality
2. Taboo, unethical, malevolent, amoral, illegal (TUMAI) and vs. Nontaboo, ethical, moral, benevolent, & legal (NEMBL)
3. Primary vs. secondary processes
4. Experience vs. nonexperience
5. Functional and practical vs. impractical, aesthetic, and
6. Synthetic vs. nonsynthetic
7. Breadth vs. depth
8. Feasible, realistic, & possible vs. infeasible, hypothetical, & unrealistic
9. Natural vs. unnatural
10. Humorous, playful, childlike, vs. serious, sober spontaneous vs. mature & responsible
11. Close vs. remote

Each of these dimensions was used in research drawing from ideas given to various divergent thinking tasks. Admittedly the results only represent the one sample, but this research does indicate that hyperspace can be examined empirically. Perhaps most important were the categories used to operationalize hyperspace. These are interesting independently of the data from the initial investigation. Here is a detailed summary of the dimensions and the method for scoring ideas using them.

1. *Originality vs. conventionality*: This dimension is about novelty and frequency of responses in divergent thinking, each of which is important because originality is a must for creativity. Empirical evidence clearly indicates that the closest associate of creativity is originality. However, creative people are not just original thinkers. They have to find a way to make the raw original ideas better, complete, and refined through evaluative and convergent thinking processes. Refinement and evaluation often benefit from common sense, conventions, standards, and goals. Therefore, routines and conformity are not necessarily the enemies of creativity. They could play a critical role in the acceptance and communication of the solutions. As a result, one would expect both original and conventional responses in divergent thinking process of creative individuals. Acar and Runco (2015) operationalized this dimension of hyperspace using an established method which relies on frequencies. Statistically infrequent responses were considered original and all others were conventional.
2. *Taboo, unethical, malevolent, amoral, illegal (TUMAI) and vs. Nontaboo, ethical, moral, benevolent, & legal (NEMBL)*: The focal point of this dimension is beneficence and social approval. Creative thinkers have on occasion been described as contrarian and psychotics who do not limit themselves to socially acceptable responses or solutions. Their ideational repertoire is wide and rich with many types of thoughts, some of which may be destructive, disruptive of established systems, chaotic, malevolent, illegal, or amoral. The fact that they do not censor themselves from thinking such a way could be a proof of their creativity because, as noted above, creativity is about thinking without limits. However, creativity is not all abnormality or anarchy. Creative thinkers may channel their divergent thinking to constructive, benevolent, legal, and morally acceptable outcomes. Therefore, one could find both types of ideas in their responses to divergent thinking tasks. Acar and Runco (2015) identified responses that were destructive, aggressive, and involving sexuality, or magical ideation. Sexuality, aggression, and magical ideation could often be viewed as taboo. All other responses were considered nontaboo and legal.
3. *Primary vs. secondary processes*: This dimension is related to the involvement of consciousness. As was previously discussed, creativity is often associated with primary processes because of its connection to the unconscious. This may help with creative solutions, especially during incubation. Primary thinking processes involve automated, fantasy-oriented, crude, dream-like, and immature that let ideas freely flow. Such as process need to be followed by secondary processes where ideational freedom is filtered by logical, sophisticated, and goal-oriented thinking. To score the responses to divergent thinking tasks, Acar and Runco (2015) used Colin Martindale's *Regressive Imagery Dictionary*, which consisted of words and concepts associated with primary and secondary processes.
4. *Experience vs. nonexperience*: This dimension is about the individual's use of memory. Remembered experience is a good source for ideation because past experiences will provide some easy solutions to some problems. Memory enhances fluency because it provides ideas, but it may also help with originality because some experiences are unique or may only be retrieved by some people. However, creative people can also go beyond their memory and past experiences and use their imagination and explore the hypothetical. It likely that imagined solutions will be more idiosyncratic than experienced solutions. It is also important to keep in mind that imagination and memory are not mutually exclusive. Imagination may be rooted in memory and experiences. The distinction between inexperienced or imagined and experienced responses was explored in previous research. Participants were able to reflect on their responses and indicate which are experienced and which are inexperienced. Thus, this dimension was scored by asking participants which of their own responses to divergent thinking tasks they had themselves experienced before.
5. *Functional and practical vs. impractical, aesthetic, and artistic*: This dimension looks into the practicality of the solutions. Things may be creative because they are aesthetic and artistic or they may be deemed so simply because of their functionality and practicality of the solutions. Creative things may resemble one or the other category, and sometimes they resemble both. One reason why design thinking became popular in creativity and innovation process is the desire to achieve both. A creative product is successful to the degree they are functional and appealing to the customers. Aesthetic and artistic aspect may help

with having an emotional connection with potential buyers while functionality and practicality will actually sell it. [Acar and Runco \(2015\)](#) evaluated each response in terms of level of pragmatism. Pragmatic uses represent the functional and practical uses of objects whereas non-pragmatic responses were for considered impractical, aesthetic, and artistic.

6. *Synthetic vs. nonsynthetic*: This dimension deals with complexity of the responses. Preference for complexity and ambiguity is among essential traits of creative people. For example, the focal point of Barron-Welsh test is to see if people embrace or avoid complexity in some drawings. Ideas may also be simple or complex and [Acar and Runco \(2015\)](#) distinguished the two by looking at the synthetic nature of the responses. If an idea combines two or more ideas, it was considered synthetic.
 7. *Breadth vs. depth*: Sequentiality is also informative to understand the processes involved in divergent thinking. The open-ended nature of the tasks allows following a consistent, predictable, linear pathway, or they could jump across distinct responses. The former is ideational progress in a vertical direction, so was called depth, while the latter refers to ideational progress in a horizontal direction, which is breadth. It may be best when people do both because jumping across categories reflects cognitive flexibility and avoidance from fixation while exploiting any single category to the fullest signifies persistence. [Acar and Runco \(2015\)](#) tracked down the sequential patterns in the responses given for divergent thinking tasks. When a subsequent response is a continuation of the preceding response semantically or categorically, it was labeled as “depth.” When there was a departure between two consecutive responses, the succeeding response was labeled as “breadth.” This method of scoring is closely aligned with scoring verbal flexibility in Torrance Tests of Creative Thinking (TTCT) based on “shifts.”
- A later study by the same researchers found that latency—the time that elapses between two adjacent responses—might predict the probability of a category switch (breadth). Latency was 5 s longer with the instances of breadth than depth. Latency took about 2.5 s longer with figural divergent tasks than the verbal ones. In a more recent study, latency also predicted originality when it was scored based on semantic networks, which assesses original as conceptual distance from the prompt. Those studies indicate that both responses to divergent thinking tasks and the process of generating them provide useful data about the dynamics of creative thinking process.
8. *Feasible, realistic, & possible vs. infeasible, hypothetical, & unrealistic*: Workability of solutions is another dimension to diverge between two poles. Some responses may be realistic, feasible, and possible while others could be just hypothetical or unrealistic. There would be limited creativity had people think within the limits of existing conditions and possibilities. Personality traits such as risk-taking and strategies like challenging assumptions may gift creative thinkers the opportunity to explore what is yet to be possible. Creative people often do that naturally, but they are still based in reality. [Acar and Runco \(2015\)](#) scored responses to divergent thinking tasks as infeasible, hypothetical, and unrealistic if they are not possible under the current conditions.
 9. *Natural vs. non-natural*: The nature of objects considered in the responses to divergent thinking tasks is another point of divergence. Surrounded by man-made objects, people may find them easier to retrieve, but natural objects may expand their ideational spectrum. The scoring procedure distinguished responses involving man-made objects from natural objects.
 10. *Humorous, playful, childlike, & spontaneous vs. serious, sober, mature, & responsible*: The responses to divergent thinking tasks may reflect the mindset. New, unusual, and flexible ideation may certainly benefit from playfulness, humor, naivety, and spontaneity while they may need to be complemented by some level of solemnity and maturity. The scoring determined responses involving playfulness and humor and labeled them as different than the rest.
 11. *Close associations vs. remote associations*: The final dimension is concerned with the distance of associations made based on the divergent thinking prompt. Most people can make common associations whereas creative people could make remote associations (see “Associative Theory”). However, making only remote associations may be indicative of lack touch with reality. Some too distant responses may be irrelevant. [Acar and Runco \(2015\)](#) identified remote associations by using associative networks from WordNet, Word Association Network, and IdeaFisher, which provided lists of associations for the divergent thinking prompts. Responses that did not use any of the concepts in the associative network were considered remote associations while those using them were close associations. They found that such as metric is related to creativity attitudes and values.

Acar and Runco tested the usefulness of this set of hyperspace dimensions using reliability analyses and concurrent validation. They administered 3 verbal (i.e., Many Uses) and three figural divergent thinking tasks and scored responses to each one for the applicable dimensions. Some dimensions were not applicable to certain tasks. For example, remote versus close associations were not scored for figural divergent tasks. Scoring involved counting how often a hyperspace category was used for each prompt. The sum of hyperspace category counts constituted the literal divergent thinking score for each participant. This score proved to be quite useful and had a significant association with originality.

Conclusion

Hyperspace is a useful framework to understand and conceptualize the process of creative thinking. One way to study hyperspace involves polarities. This is an especially good way to study hyperspace because decades of research underlines the importance of dealing with opposites and polarity in thinking for creativity. Clearly, this framework is well-situated on the conceptual and philosophical foundations and relevant theories of creative personality support it. This entry elaborated a specific application of hyperspace to divergent thinking. Hyperspace is a novel approach to score divergent thinking tasks in several ways. First, it focuses on the

processes involved in ideation. Second, it truly reflects “divergence” and hence is consistent with the very definition of divergent thinking. It captures a kind of divergence—literal divergence—that typical applications of divergent thinking tests does not. Third, it is highly operational compared to the frameworks of complex personality traits. Fourth, it is an integrative approach covering a wide variety of theoretical and conceptual bases. However, it has certain limitations, too. For example, the dimensions may further be expanded to others such as “abstract vs. concrete.” Second, some dimensions (e.g., close vs. remote; primary vs. secondary; originality vs. conventionality) are more objective than others in terms of scoring, which allow automated scoring. Third, scoring divergent thinking tasks for 22 dimensions is laborious. Future research may focus on a revised version of the hyperspace categories that are both extensive and highly objective.

Idea Density

Idea density (ID) is a well-known psycholinguistic measurement method to study the processes in language. ID separates words and sentences from the conceptual meaning in the text and analyzes the density of ideas in written or oral works. An ID score is calculated by dividing the total number of verbs, adjectives, adverbs, prepositions, and conjunctions in a work by the total number of words. ID is important to as it allows creativity researchers to study the relationships between ideas, language patterns to present those ideas and creativity.

ID formulates both linguistic and technological approaches to reveal how people express their creativity in written or oral works. Writing reveals insights into their author's personality, education, background, culture, and psychology. The ways that authors introduce and explain ideas, connect them to each other, and their word choices all say something about them. Many psychologists and government bodies use writing samples to unveil details about the person and to understand their psychological nature. Forensic and historical detectives use writing to situate authors and their work leading to clues about their lives and mindset. Like fingerprints, authors and their writings are unique. However, the languages that authors follow patterns of speech and people learn to set up their writing according to these patterns. These patterns begin in preschool and continue to be developed throughout the education system creating writers that use these patterns of speech even if they don't recognize them as such. ID helps researchers formulate ways to study people's writings in order to learn more about their ideas. By parsing out the density of ideas, ID studies the core thoughts and thought processes beyond the text on the page.

Some authors make elaborate sentences with flowery, wandering language. Some authors are succinct and direct. Some people show their emotions, while some do not. The impact of the word choices counts when it comes to writing. You may see hundreds of pages notes on one topic, but in those hundred pages only a handful of ideas are presented. Alternatively, you may see two pages of text that is laden with ideas. ID comes to the play here to distinguish the different level of densities of ideas in written works. In this example, the hundred pages work may have the same or even fewer ideas than the two pages work.

Creativity happens in verbal and non-verbal ways, but when authors talk about creativity it is verbal. In a soccer game there are certain words or phrases used to describe what is going on during the game: *pass*, *run*, *defense*. A soccer commentator can talk for hours by only using few words to describe the movement and creativity of the players during the game. Similarly, an artist employs creativity in a number of ways, but when that art is discussed by others there are certain words or phrases used to describe the work: *aesthetics*, *abstracted*, *vivid*. In both the soccer and art commentaries, authors express their creative ideas with using a few certain words or phrases according to Turkman and Runco's (2019) study. For example, using *however* means that a person is going to

make a counter argument to explain something different than usual situation. *However* is a cue that the person is going to bring a different perspective to the situation. In the soccer example: Player A has a great record with free kicks, *however* he is returning from surgery and may not be at his best. In the artwork example: Artist A is an excellent watercolor artist, *however* she has recently been experimenting successfully with sculpture. Turkman and Runco (2019) revealed the relationship between language and creativity by focusing on how people use these kinds of keywords to introduce their original ideas.

ID helps us to determine the conceptual meaning underlying text as the superficiality of the words and sentences are separated from the conceptual meaning in the text. It is a mathematical way to quantify ideas and make the quality of the work tangible to understand what ideas exist beyond the sentences. When you are happy you use different words or gestures to show what you feel. When you are sad you use completely different words or gestures to express how you are feeling. During this process different psychological and physical factors involve our language and our bodies to express our ideas or feelings. In English there are only 26 letters. Authors present their ideas and themselves by using these 26 letters. Some earn a Nobel Prize by using these 26 letters; while some fail their final exams using the same 26 letters. What is important here is how authors communicate ideas and the creativity of those ideas.

The Background of Idea Density

In the 1960s Walter Kintsch, a psychologist, began working to understand how people encode and decode written texts. In this framework, authors encode meaning into written text and readers decode meaning from the written text. Kintsch's work was influenced by the earlier work linking the perceived difficulty of a text to its readability and communicability. In 1973 Kintsch and Keenan found that the propositions in a text influenced the reading rates and the encoding and decoding processes of the text and published what would become the foundations for the Idea Density, or ID, theory.

Ideas and Propositions

Turner and Greene later used Kintsch and Keenan's (1973) propositions or "representations of conceptual units" (1977, p. 4) where the proposition itself represents a concept that is more than the words used in the text. At first an idea is pre-positional because it exists in the mind of the author alone. The idea becomes propositional once language is employed to describe it. For Kintsch, language is the expression of thoughts made at this propositional level and Kintsch was deeply interested in how to understand the psychological representation of meaning (Thorson and Snyder, 1984). Turner and Greene (1977) formed a methodological framework for this representation of meaning by using propositional analysis. For example, the sentence: *The young brown dog has very large ears* contains 5 propositions:

1. Has/dog/face: *The dog has a face.*
2. Young/dog: *The dog is young.*
3. Brown/dog: *The dog is brown.*
4. Large/ears: *The ears are large.*
5. Very/large ears: *The ears are very large.*

Propositions are conceptual units that are independently true or false. The dog may be young, but may not be brown. Likewise, the dog may not be young, but the dog may be brown. An ID value of the example sentence is determined by the number of propositions divided by the total number of words in a text (Kintsch, 1974; Turner and Greene, 1977). To calculate the ID value, the propositions in the sentence are divided by the total number of words in the sentence leading to an ID value = $5/9 = 0.55$. As measure of quality, ID value determines the efficiency with which ideas are explained. That is to say that any additional descriptive elements or qualifiers about our dear dog would count as additional propositions, but the additional word counts balance out the overall rating so that excessive or flowery language does not increase the ID value. It is also important to note that ID propositions do not include common nouns, verb tenses, modality, or co-references (Kintsch, 1974).

Propositional analysis and ID values have been replicated in various studies. Covington conducted a study where text documents about the same news event were analyzed for ID value and then comparisons were based on the genre of the news type (2009). In the Covington study there were four genres: Popular, Introductory, Scholarly, and Technical divided by the intended audience for the reporting. Popular news sources included news outlets such as Bloomberg and USA Today. Introductory sources included Wikipedia and other blog-style entries. Scholarly sources were those written for academia and Technical sources were written for policy makers. Covington contributed to the development of a computer analysis program called CPIDR to find that both popular and introductory sources had ID values of less than 0.5, while the scholarly sources hovered around the 0.5 mark and all the technical sources exceeded 0.5 meaning that these technical sources presuppose the audience knows a great deal about a specific topic and therefore, these authors can immediately and compactly present ideas. Compared to a popular or introductory source that must first explain basic ideas to a general audience before introducing new ideas, the technical authors can be more succinct and efficient in their presentation of ideas (Covington, 2009). Propositional analysis and ID values are promising tools for evaluating texts and from Covington's study it is evident that the same information presented in different ways for different audiences is communicated with different levels of ID.

Computerized Propositional Idea Density Rater (CPIDR)

The CPIDR (pronounced “spider”) program was developed to make part-of-speech tagging analysis feasible for research purposes. With the development of CPIDR, the laborious counting system to determine ID value was alleviated and currently CPIDR5.1 is available to the public for ID value calculation. CPIDR provides the originality level for thousands of pages of written works in seconds, rather than weeks or days.

With the help of programs like CPIDR, Kintsch’s ID value method one of the most widely used validated systems in psycholinguistic research. ID is more than a theory of semantic logic; rather ID is a theory of how our minds process information. Kintsch’s system has helped researchers go beyond the text and study the cognitive processes in making that text. Assessing the density of ideas contained in a text has potential to further the way researchers evaluate creativity. The CPIDR program makes Kintsch’s method of analyzing language easier. It automatically finds all the prepositions in the text and divides it by the total number of words rapidly calculating the ID of thousands of different texts. Creativity researchers are aware that the ability to generate original ideas is critical to creative thinking and creativity researchers have developed many ways to assess creative products and extrapolate creative potential from the creative product. For example, the Consensual Assessment Technique, or CAT, developed by [Amabile \(1982\)](#) does just that by asking participants to create products that are then assessed by experts in that field. This product-centered approach and the extrapolation of creativity parallels the text-centered approach of ID and the potential of ID to extrapolate creativity as well.

Idea Density and the Cognitive Processes of Creativity

The studies about cognitive processes related to the generation of ideas come from a number of disciplines signifying the broad interdisciplinary nature of ideation and the study of creativity. Cognitive reserve, divergence, and memory, mental leaps, and semantic distance originated in cognitive studies. ID offers a new approach to assessing creativity by using cognitive research creating a theoretical foundation for ID as a research method.

Idea Density, Cognitive Reserve, and Divergent Thinking

ID has been used a measure of cognitive “reserve” ([Stern, 2002](#)), which is to say that people with higher levels of cognitive reserve process tasks more efficiently than their counterparts. Stern noted that high cognitive reserve individuals often test with higher intellectual capacity and educational or career achievements, and that these individuals can cope with higher levels of brain damage (i.e. dementia) before exhibiting any functional decline (2002). In fact, in a longitudinal study lower ID scores as a young adult were proven to be precursors for dementia later in life ([Snowdon et al., 1996](#)). Stern described cognitive reserve as “the ability to optimize or maximize performance through differential recruitment of brain networks, which perhaps reflect the use of alternate cognitive strategies” (p. 451) and this aligns with the work of creativity researchers—particularly those researchers using Divergent Thinking, or DT, tests to assess creative potential. In a DT test a participant responds to open-ended questions to measure the ability of a participant to think in novel and original ways. DT tests have been the “backbone” of creativity assessment for decades and creativity researchers continue to value the data and analyses of these tests because they provide some understanding of how those ideas are formed and particularly how the brain works in the formation of these new ideas. DT tests aim to capture the quality of the divergence of the responses. Furthermore, DT responses are scored on flexibility, fluency, originality, and elaboration as the assessment is aimed to determine the quality of the ideas and their divergence from typical responses. There is a relatively higher correlation between originality and fluency in DT meaning that when people have more ideas, the potential of having original ideas are higher. Like DT, ID is aimed to distill the quality of ideas parsed from the complexities of the sentence structure and language. Both measures are trying to understand how creative ideas are generated and both measures value the quality over the quantity. Idea density, cognitive reserve, and DT all garner the efficiency of a participant to generate creative ideas and this is important to the study of creativity as creativity thrives on ideation.

ID and Working Memory

Memory and the ability to recall information are integral to the cognitive processes in generating ideas as well. [Ericsson and Kintsch \(1995\)](#) proposed that working memory is comprised of the well-known short-term working memory (STWM), but added the component of a working memory linked to long-term memory, which they called: long-term working memory (LTWM). This LTWM is memory that available in a space between long-term memory and short-term working memory and LTWM is initiated by retrieval cues during a task. It had been proven that ID determined the amount of work a reader had to do in order to read a text, but that if the reader were familiar with the domain of the content of the work, the ID has less influence on reading rate ([Miller and Kintsch, 1980](#)). Ericsson and Kintsch found in their 1995 study that there were differences in the LTWM of skilled and unskilled readers in reading span tests. While both groups utilized the capacity of their STWM, the skilled readers were also able to access their LTWM of the domain, thereby expanding their total working memory. This expansion of the concept of a working memory and the macrostructures and microstructures of working memory’s composition are important factors when determining the cognitive processes in generating ideas, particularly in generating original ideas. [Kellog \(2001\)](#) found that the ideas of STWM and LTWM were also evident in the writing of text. In the acts of both reading and writing of text people are accessing more of our

minds than our STWM to translate and conceptualize the words—people are conceptualizing the words based on our experiences with them enlisting our LTWM with that domain.

ID and Mental Leaps

As new ideas are conceptualized there is a reliance on memory in many ways and the information individuals have experienced in the past influences these new ideas. [Thorson and Snyder \(1984\)](#) used the ID propositional structure of advertisements to evaluate which ads were better remembered—better coded—by participants in terms of the quantity of ideas, the information retained from the ad, and the use of branded or descriptive words a day after viewing the ad. Their ID-based “Ad Language Model” successfully linked the propositional structures of the advertisements to improved recall of the ad messages. Understanding how ideas are encoded into memory structures and how ideas are expressed is of vital concern to creativity research and ID offers an approach to discover these relationships and processes.

Ideational pathways, including divergence, memory activation and recall as previously mentioned, have drawn the attention of creativity researchers. There are a few lesser-known conceptual models for ideation in creativity. E.P. Torrance is one of the pioneers of the mental leap concept in creativity. [Torrance \(1995\)](#) defined the ability to take mental leaps as an important aspect of DT as they demonstrate the resistance to premature closure. [Turkman and Runco’s \(2019\)](#) study also investigated cognitive processes in the associative processes taking place in DT by focusing on how semantic distance is related to traditional flexibility scores. As originality and appropriateness are two important defining factors of creativity, the identification of the relative distances of these ideational pathways’ in our cognitive process is important to determine if the idea fulfills the originality and appropriateness criteria. In other words, a very far distance of ideational pathway might represent an unrelated and inappropriate idea.

Idea Density and Keywords

Significant relationships have been found with regard to creativity as in [Turkman and Runco’s \(2019\)](#) study investigated keywords—the common words and phrases that are used to introduce original ideas—and compared the density of keywords in a work to the ID in the work.

Keywords are the specific words and phrases that are used with regularity when people introduce a new idea. Remember the example, however that typically introduces a counter-argument and therefore an idea. Experts created and compiled a list of words found in various oral and written works. Upon reaching a consensus the final list contained 17 words that the experts identified as keywords most often used to introduce ideas. Some keywords introduced an original idea, while other keywords introduced a contradiction or possibility (e.g., “possible”, “would be”). The keywords were coded into a computer algorithm and the oral and written works were analyzed for their keyword usage. The statistical analyses indicated that the keywords successfully identified original ideas in written works and speeches. This study revealed general tendencies and a set of particular keywords that are used with regularity when people introduce a new idea.

Unlike ID, the density of the keywords was calculated by the total number of keywords divided by the total number of sentences. This was done to control for the fact that ideas that are introduced with keywords occur during the course of the sentence so it would not be meaningful to divide by the number of total words as in ID values. Upon comparing the data from the keywords algorithm and the CPIDR ID values, the results revealed that there was a large and significant correlation between keywords and ID.

[Runco et al. \(2017\)](#) study also showed that the higher frequency of ID was related to both reputational change obtained from encyclopedic entries and in terms of [Ludwig’s \(1992\)](#) Creative Achievement Scale (CAS) designed to measure the creative accomplishments of deceased individuals based on information extracted from biographical sources. This study investigated these eminent people writings and calculated their ID values by using the CPIDR. The results indicated that CAS and ID have a statistically significant relationship. In other words’ ID can be a predictor of creative achievements. [Turkman et al. \(2019\)](#) study also took the ID method into consideration to test the keywords method’s functionality, which is based on general tendencies of introducing original ideas in sentences. The ID method also here showed a significant relationship with [Turkman and Runco \(2019\)](#) keywords method.

Four Applications of Idea Density in Creativity Research

Ideas play a critical role in creative thinking and innovation. Hence, many creative potential tests focus on ideas. These four creativity research studies were conducted between 2015 and 2017 and they each employed ID in the study of creativity ([Runco et al., 2017](#)). The overarching goal of all four studies was to see how ID could be applied to traditional creativity research methods in order to evaluate ID’s practical and methodological usefulness to the creativity research field. Each of the four studies applied ID differently to assess creative potential or achievement as identified with conventional creativity research methods.

The first study examined the relationship between ID and citation impact (CI). CI often is used to measure the quality of research articles and thus the eminence of the researcher. It is reasonable to postulate that works that are dense in ideas (high ID) would be cited more often compared to works that are less dense in ideas (low ID). The findings supported that ID was positively correlated with CI, confirming that articles that are denser in ideas are more frequently cited.

The second study investigated the connection between ID and eminent people. It is reasonable to consider that eminent people present works that have high ID values. In this study the writings of eminent authors was compared to the ID of their published works. Level of eminence was calculated in previous archival research on reputation and creative achievement. The findings supported that ID was positively correlated with the creative achievement rankings. ID was also positively correlated with positive reputational changes, meaning that those writers who had higher ID values also gained greater fame as their careers progressed.

The third study analyzed the relationship between ID and Divergent Thinking (DT). DT tests are typically scored according to four criteria: fluency—the number of ideas, originality—number of new and unusual ideas, flexibility—number of connections among different areas and ideas, and elaboration—details about the ideas. Previous creativity research has demonstrated a positive correlation between fluency and originality (Hocevar, 1981) meaning that originality comes with more ideas. The findings confirmed that ID was positively correlated to both the DT test and to the Runco Ideational Behavior Scale. This supports the claim that people who demonstrate high levels of ID are divergent in their thinking and more frequently engage in creative behaviors.

The fourth study examined the ID of TED Talks correlated with the “hits” the talk logged online. In this study it was shown that people like to watch or listen to TED talks that contain more ideas demonstrating that ID is indeed an important factor to evaluate the quality of written or oral works as determined by public interest.

Together these studies showed that written and oral works with higher ID values made larger impacts on others and gained more attention. This concurs with what is known about how people value ideas. People check their phones increasingly often during the day. Each time they check their phone they get new information from messages, apps, notifications, etc. This interaction gives them new information consistently. It is like a reward for seeing something new all the time and this motivates them to use their phone more and more because this is part of their nature. Individuals tend to repeat actions that are positively reinforced. So if ID measures the density of ideas, and those “denser” works reach more people, then it is in the best interest of authors to create work that considers this desire for new information in a concise format. Readers and listeners want authors and speakers to get to the point and present them with new and exiting information during the interaction.

General Discussion

The Four Application Studies confirmed a priori expectations: high ID values correlated to high assessment of creative performance and influence. Each of the four studies contributed a dimension of how ID can be used alongside creativity assessment methods for more nuanced perspective of how creative ideas are made and how they influence others. Since ID is a measure of density and therefore efficiency, the “richness” of a work is important for evaluating and assessing the performance of creativity.

In creativity literature there continues to be a primary concern about fluency’s possible contaminating effects where fluency counts the total number of all ideas that a person produces during an assessment. In many studies of creativity it was seen that originality follows fluency. The more ideas generated, the more likely it is to have a higher number of original ideas leading researchers to term this “fluency’s contaminating effect.” In other words, fluency is an active factor in DT tests’ scoring, especially in originality scores because the likelihood of having “original” ideas follows the generation of a greater number of all ideas.

The most recent definitions of creativity focus on two main qualities to describe an idea as creative: original and useful. So, if an idea is not original or useful, it cannot be creative. However, original ideas do not necessarily come to our mind immediately. Individuals need to exhaust the list of our everyday ideas to arrive something new. No one tries to start a fire with rocks and sticks until they run out matches or are without a lighter. If DT tests show that people who have more ideas (fluency) tend to have more originality scores, then it can be said that by looking at these four studies that generating all kinds of ideas are prerequisites for generating original ideas. Instead of looking at the mirror from the reverse and saying that fluency contaminates originality, it should be said that fluency contributes to originality.

These studies made clear that there are significant correlations between ID and creativity. As ideas are critical to any type of creativity, this work should continue to develop new ways to use ID with creativity assessment in the future.

Further Directions

It must be noted that the technological advancement for conducting these studies was vital to their success. ID calculations would be extremely resource intensive if it were not for modern computers and programming. It is envisioned that as the technology improves, it will be possible to calculate even more text at even faster rates. It also is possible for new algorithms to be developed that are more sensitive to language patterns and specifically to the differences in written and spoken language. Currently, CPIDR and the keyword algorithms are only available in English, which immediately limits their usefulness. Refining and expanding the programs’ language capabilities is critically necessary to further this research. There also is an opportunity to merge these various programs to behave more like the battery of tests that are now used in creativity research. ID can and should be part of that discussion. Ideas and how creative people arrive at creative ideas will remain a primary topic of creativity research. What ID offers is another tool to try to understand that process.

Glossary

Flexibility The use of diverse conceptual categories. Thinking that is varied rather than rigid.

Fluency The number of ideas produced on a divergent thinking (idea generation) task.

Immediate Creative Product Ideas, insights, and other outcomes of the creative process that go no further (e.g., there is not sharing or social recognition).

Intermediate Creative Product Creative activities and accomplishments that are socially recognized and not just personal, but at the same time are not world-shaking. They do not change the way other people think in any lasting way, unlike ultimate products.

Originality The novelty or unusualness of products and ideas.

Ultimate Creative Product Outcomes of the creative process that are very widely recognized and which have broad impact, changing the way that other people (besides the creator him- or herself) thinks.

Valuation Finding value in ideas. Valuation can be contrasted with critical thinking which finds flaws.

Introduction

One major approach to the study of creativity focuses on outcomes and products. Other approaches focus on the creative personality, creative places, and creative processes, but the product approach is quite common, probably because products can be studied more objectively than those other things. After all, products tend to be manifest and are less elusive than many other aspects of creativity. There are different kinds of creative products.

The Utah conferences on creativity from the 1960s included discussion of *ultimate creative products*, *intermediate creative products*, and *immediate creative products*. Ultimate creative products are often professional and always socially recognized as creative. They may be famous and, at the highest levels, change the way others think about the world. Intermediate products may win awards but may not be world famous. Audiences will agree that intermediate products are creative, but an intermediate product may not change the way others think, at least in any global enduring manner. Immediate products may not be socially shared nor recognized. They are common in everyday creativity and may be some sort of new understanding of the world by one individual. Indeed, the theory of personal creativity defines creativity as the construction of original and effective meaning for the individual. Hence the product is a new understanding which is created by the individual. Immediate products may also take the form of simple insights, solutions, or ideas that are original and effective (and thus qualify as creative) for the individual, but only for the individual, in part because they are not always shared with others.

The most common immediate product studied is the idea. There is a large literature on ideation, no doubt because the creative process often begins with an original idea. That process may refine the idea, share it, publish it, and promote it, in which case it may be transformed into an immediate or ultimate creative product, but at first there is just the idea.

Many tests of creativity give examinees open-ended tasks and allow them to generate as many ideas as they can. The resulting ideas are then typically scored for *fluency* (the number of ideas), *originality* (the uniqueness or novelty of the ideas), and *flexibility* (the number of conceptual categories used by the individual and apparent in his or her ideas). Importantly, ideation can be objectively assessed with these tests. The tests are reliable and, when used correctly, they have more than adequate predictive and discriminant validity. Interestingly, the investigations of the predictive validity of tests of ideation often use intermediate products as criteria, the logic being that when a person has numerous ideas, some of which are original, he or she is likely to produce socially meaningful creative things as well.

Ideas seem to be useful for creative efforts and are certainly useful in research on creativity. Creative work does not, however, depend solely on the production of ideas. There are influences on the production of ideas (e.g., attitude, affect, motivation, knowledge) and, once ideas are generated they need to be evaluated. Very likely a person will generate ideas but reject many of them and

then continue to think about and perhaps refine those that pass muster. In many instances there is also an inter-personal evaluation of ideas. This Encyclopedia entry will review research on the part of the creative process where ideas are evaluated.

Empirical Research on Idea Evaluation

One very useful method of idea evaluation involves two phases. First ideas are collected; a sample of examinees receives tests of divergent thinking and produces a large number of ideas, some of which are original and some of which are common and unoriginal. The exact degree of originality is determined, for each idea, by checking statistical frequency. Hence an idea given by only one person in the sample is unique and given the highest originality score. Ideas that are given by most examinees are common and given a low originality score. Ideas in between are given intermediate originality scores.

This process can be quite precise. It can, for example, use exact probabilities (Runco et al., 1987). This means that the exact frequency of occurrence in the sample is used when calculating the originality score, and that score can be taken as a kind of probability (i.e., the likelihood that the person will produce original ideas in the future). This line of research on idea evaluation is not concerned with predictive validity, however, so the important thing is the exactness of the score. Suppose there was a sample of 100 examinees. Suppose also that 90 of them gave one particular idea in response to the divergent thinking question, "name round things." That idea might be "basketball," just to be specific. The originality score for "basketball" is therefore 0.9 (90/100). For simplicity of interpretations this score is usually inverted by subtracting from 1.00. That just allows high originality to have a high rather than a low score. In the case of 0.9 the score becomes $(1.00 - 0.9 =) 0.1$, which is a low originality score and makes sense because so many people in the sample (90% of them) thought of the same idea. One further convenience that is often used is to multiply by 100 (much like the original IQ calculations) which just creates whole numbers. Thus 0.1 becomes a score of 10. What of an idea that was only generated by one person or very few people? Suppose 5 people gave the idea "Pluto" to the "Round things" question. The originality of that idea would be $(1.00 - 0.05 =) 0.95$ and then 95, which is very high (relative to the maximum of 100). These scores can be interpreted much like a percentage since the scale is the same (zero to 100).

This particular method is used to determine the originality of ideas. These ideas will be subsequently used in phase two of the research on idea evaluation. The method being described here is not being used to determine the originality of the examinees, though that is the objective of typical divergent thinking testing. Phase two in the work on idea evaluation starts by selecting a group of ideas from phase one. They may be randomly selected, though that is not necessary. Indeed it is best to select ideas that represent high originality (e.g., scores of 90 and above), intermediate originality (e.g., around 50), and low originality (e.g., below 20 or even 10). Research often uses about 10 of each of those. They are placed on a new survey, at which point the arrangement should be random. Each idea is used as one item or question in this new survey. In much of the research each idea is associated with a Likert scale and instructions ask respondents to rate each idea in terms of originality. If the respondent is good at idea evaluation highly original ideas should receive the highest rating on the Likert scale, moderately original ideas should receive a middling Likert rating, and the least original ideas should receive the lowest Likert rating.

There are alternatives. Respondents taking the new survey can be asked to simply identify which are the most original ideas (without a Likert scale) and an accuracy score then based on the number of highly original ideas (determined by phase one) each examinee correctly identifies. Another method has been used with school-aged children. It uses a Likert scale but instead of numbers and words happy faces response options are used; a very happy face takes the place of the highest Likert response option and a frowning face takes the place of the lowest Likert rating. Varying degrees of smiles or frowns replace all response options. Quite a bit of work has demonstrated how well this happy face method works with school children.

School children have also been asked "how many of your friends are likely to give this idea?" instead of "rate the ideas for originality." That is because children may have an easier time judging the former (how many friends) than the slightly more abstract "how original?"

Another variation involves the rating criterion. In the example above originality was targeted but research has also asked about the quality of the idea (i.e., its effectiveness or usefulness) and the popularity of the idea (in case it is easier to judge the opposite of originality than the infrequency of ideas).

It is fairly easy to summarize the key results of this line of research:

In the first investigation using the two-phase methodology just described, Runco and Vega (1990) collected data from both parents and teachers who were asked to evaluate the ideas given (in phase 1) by children. Runco and Vega were especially concerned about data on the fourth grade slump, which at the time of this research was reported to manifest itself in about 50% of the fourth grade children in USA. The parents and teachers also received their own divergent thinking tests. That was because one hypothesis was that idea generation is related to idea evaluation. Analyses indicated the following:

1. Parents with more children were more accurate than other parents when evaluating children's ideas.
2. Ratings of the popularity of the ideas were significantly different from ratings of the originality of the ideas, which supported the idea that parents and teachers do, at least implicitly, recognize that original ideas are uncommon and in a sense unpopular.
3. The accuracy of the ratings given by parents was not significantly different from the accuracy of the teachers. Both were accurate at approximately the same level and neither group differed much from adults who were neither parents nor teachers.
4. Divergent thinking scores were correlated with evaluative accuracy. This was interpreted as an indication that people who give numerous ideas have more practice evaluating ideas than others and as a result are better at judging ideas.

Not long after that report was published [Runco \(1991\)](#) used the same two-phase methodology with children (rather than adults). One interesting question involved a theory in the creativity research at that time, namely that children were not actually creative at all. In this theory children are accidentally original in their thinking and ideas, and they think and share things that seem to be original to adults but only because the children do not know any better. Adults attribute creativity to these children, in this theory, because they are surprised by the ideas, but the ideas are not actually original, just uninformed. Note the assumption here that creativity is intentional. That is debated in various lines of creativity research, including that which discusses how to best define creativity and that which discusses moral creativity (see [Runco, 1993](#)). The research conducted in 1991 also gave children (in phase 2) divergent thinking tests so the relationship of idea generation with idea evaluation could again be examined. Analyses indicated the following:

1. The idea evaluation measures were highly reliable. That was an important result because it was possible that children would have difficulty with the idea evaluation surveys or that their idea evaluation skills were not yet mature.
2. Divergent thinking (idea generation) was again significantly correlated with idea evaluation accuracy, but the correlation was only moderate. To be precise just under 40% of the variance in the divergent thinking and idea evaluation scores was shared.
3. Idea evaluation accuracy was unrelated to intelligence test scores (i.e., the WISC-R IQ test), which supported the discriminant validity of this kind of evaluation and suggests that children who have high IQs might not be good at evaluating ideas. This is consistent with research on divergent thinking, which is also typically unrelated to IQ.
4. There were instructional effects in that children were the most accurate at evaluating ideas when they were told to estimate the number of other children who would think of each. In short, judging popularity was easier than judging creativity. It is not much of a surprise that it is difficult for children to judge creativity per se, given that it is an abstract concept. Yet given that popularity can be judged accurately, and given that popularity is antithetical to the originality that is required for creativity, it may be that there is a method implied here that would help children judge creativity or increase the originality of their ideas and solutions.
5. Idea evaluation accuracy was unrelated to the age of the children. This could reflect the restricted range of ages. Also, there were no differences between girls and boys in terms of evaluative accuracy.

It is likely that somewhat different processes and criteria are used when judging one's own ideas vs judging ideas given by someone else. For this reason [Runco and Smith \(1992\)](#) compared inter- and intra-personal idea evaluations using the same two-phase methodology. They also administered a "preference for ideation" measure to determine if attitudes were involved in idea evaluation. The key findings were:

1. Canonical analyses were used and confirmed that there was a statistically significant correlation between inter- and intrapersonal evaluative scores. They shared about 40% of their variance.
2. Interestingly, there was also a significant correlation between divergent thinking and intrapersonal evaluative accuracy.
3. There was another significant correlation between the preference for ideation attitude and interpersonal evaluative accuracy.
4. Participants were significantly more accurate when they were asked to evaluate the uniqueness rather than the popularity of their own ideas, but significantly more accurate when evaluating the popularity rather than the uniqueness of ideas given by others.
5. None of the evaluative accuracy scores were very impressive. The highest percentage of correct identifications was for interpersonal evaluations, where 42% of the popular ideas were correctly identified. The lowest category was intrapersonal evaluations, where only 21% of the popular ideas were correctly identified. These results are quite important and suggest that people may not be very good at judging the originality of ideas. That could easily get in the way of efficient creative problem solving and, in this light, may point to a target for creativity enhancement efforts.
6. Both intra- and inter-personal evaluative scores had discriminant validity. Both were unrelated to standard measures of critical thinking. This extended the finding above where evaluative accuracy was unrelated to IQ scores.

Min Basadur presented a very useful model of creative problem solving that includes evaluative accuracy, as well as idea generation and attitude. This model was developed for use in organizations. With that in mind the next research project examined the evaluative accuracy of managers. [Basadur, Runco, and Vega \(2000\)](#) were also interested in improving creative problem solving so administered a program to improve ideation. Four styles of creative problem solving were assessed, namely labeled generator, conceptualizer, optimizer, and implementor. Analyses indicated that the training improved the evaluative accuracy of the managers. The impact of training was moderated by the conceptualizer style of thinking and by the "preference for active divergence" attitude. The relevance of these two things implies that accurate idea evaluation might be predicted from certain characteristics, at least among managers.

[Rietzschel et al. \(2014\)](#) also took a practical approach to idea evaluation. Their interest was in brainstorming groups. As they described it the typical brainstorming group leads to an increase in idea quantity but not quality. That is probably because brainstorming has three guidelines, and one of them is "quantity over quality," the message being that the group should not worry about quality, nor evaluating ideas as they are produced, but instead should focus on making sure that the largest possible pool of ideas is generated. This makes the most sense when a second guideline is acknowledged, namely "postpone evaluation." Note that the guideline is not "eliminate evaluation." Creative ideas must be effective as well as original so at some point an evaluation is vital; but evaluation can be postponed until late in the process, after a large pool of ideas is available. The third guideline is "hitchhiking," which is a simple method whereby each individual attempts to extend the thinking of other individuals. Rietzschel et al. collected data from various brainstorming groups and manipulated *problem scope* (broad vs narrow) and group instructions (emphasizing

personal relevance vs idea creativity). Analyses of the output indicated that the instructional type and the problem scope were related to the evaluative accuracy within the groups. In particular the groups preferred more creative ideas when they had received creativity instructions and when the focus was on a narrow problem scope.

de Buissonjé et al. (2017) also started with the notion that evaluative accuracy could be improved. Their method differed from the one used in the series of studies described above, where there were two phases. de Buissonje et al. presented research participants with 18 ideas and asked that the five most creative ones be selected. The procedure to improve selection involved inducing positive affect as well as a promotion focus (via a self-affirmation task) before the ideational measures were presented. Both of these pre-evaluation manipulations were indeed likely to influence selection accuracy. Positive affect, for example, is frequently associated with creative performances, the idea being that individuals who are in a good mood are more open minded and consider a wider range of solutions than otherwise. Analyses confirmed that positive affect and the promotion focus did lead to increased accuracy.

Discussion

The research on idea evaluation is in its infancy compared to the research on the generation of ideas. Still, some headway has been made, as is evidenced by the research summarized in this chapter. This research indicates that there are differences between inter- and intra-personal evaluations and that there are various influences on the evaluation process. Attitudes, creative styles, affective states, problem scope, and promotion focus were all examined in the research and found to relate to evaluative accuracy. The research is, in this sense, consistent with the idea of a creativity complex. Creativity is not a unitary thing but instead involves different processes and is influenced by a variety of factors, some cognitive, some extracognitive.

The differences between inter- and intra-personal evaluations are especially intriguing. They might be explained in terms of the available information or in terms of divergent perspectives. Someone judging his or her own ideas will, for example, have information about context and associative history. They will know where any one idea came from, what it was associated with, and what else was in the same associative chain. This may lead to low originality evaluations because if a person produces a chain of associations and the ideas are each related to one another, any one idea may appear to be much like the others and thus not all that original. Other people would not have that same information and thus might see the same idea as highly original. They would not be aware of all of the similar ideas that might have been considered by the person producing the ideas and in the same associative chain. Interpersonal judgments differ from intrapersonal evaluations, in part because the former have no information about associative histories.

One implication of the research on idea evaluation can be directed to other research on creativity which involves judgments and raters. There is quite a bit of research that uses judgment and raters, including that relying on the *consensual assessment technique*. That method was developed to study the impact of various social conditions on creative outcomes. It was initially used to produce ratings of products such as collages and poems, but it has been used to collect data on a wide range of other products as well. It does depend on judges, and the research on idea evaluation suggests that there may be differences among groups such that one group will offer ratings that may very well differ from ratings given by another group. The problem is, then, that the validity of ratings may not generalize, so the results of any one study, using any one group, may not apply to other groups.

Certainly more research is needed on the topic of idea evaluation. The research summarized in this chapter used several different methodologies, which means that results are difficult to compile, and there is not enough data available for a meta-analysis. The only marginal correlation between idea evaluation and idea generation indicates that these represent two fairly distinct skills, and models of the creative process recognize both—along with some sort of problem finding or problem identification skill. This too implies that more research is needed specifically on idea evaluation. It is an important part of the creative process, and probably the part where the least amount of empirical information is available.

Imagery

Mental imagery is a form of internal representation that occurs spontaneously or deliberately in the human mind. It can refer to any sensory modality (visual, auditory, olfactory, gustatory, tactile, motor or kinaesthetic), involved in seeing in the mind's eye, hearing in the ear's mind, smelling in the nose's mind, and so forth. This means that imagery resembles perceptual experiences representing information stored in long-term memory, as well as events of various type (e.g., past experiences, future scenarios), spatial relationships between the parts of objects or locations of the sensory stimuli, and movements. Imagery is also a means of symbolization, because it stands for information originally perceived by our senses, which is replaced by conventional signs, and for information that emerges by merging different sensory elements of ideas, for example when the mind is engaged in creative thinking. In other words, imagery is a representational medium of both modal (sensorimotor) and amodal (spatial and symbols) information. It facilitates thought processes, supporting different cognitive operations, including imagination and fantasy, that rely on a broader concept than simply the imaging of a stimulus, event or symbol. Indeed, imagination or fantasy involve elaborated cognitive activity that is based on sequences of stimuli and events that recombine the content of the thought in new images and ideas.

Across years the idea that imagery is also an essential component of creativity has increasingly attracted the attention of the scientific community. It is assumed that creativity can benefit imagery because it is flexible and allows combining multiple elements into new ideas, as well as to favor pattern discovery, mapping relationships or regularities between things into general mental representations or mental models.

The association between imagery and creativity has been hypothesized primarily on the basis of the numerous anecdotal accounts that have been reported by artists and scientists. One of the most famous example is Kekule's dream about a snake seizing its own tail, leading to the discovery of the Benzene structure. Others accounts highlighted the importance of voluntary manipulation of images during the creative process. Nikola Tesla used mental images of mechanical models that ran for several weeks to understand which parts of his inventions (e.g., self-running engines) could be subject to premature wear. According to these reports, discovery and creativity would arise more or less directly from visual images. However, non-visual imagery modalities have also been suggested as being involved in creative processes. Mozart and Wagner essentially claimed that they were supported by auditory imagery during their compositions. These and other anecdotal accounts reveal that imagery is a language of discovery, that can occur in parallel with spontaneous or unconscious thinking or with deliberate thinking.

However, at the empirical level, the association of imagery with creativity is not always clear and expected, because it varies as a function of individual differences in imagery abilities, cognitive style, domain of knowledge (e.g., visual, musical, olfactory, motor contexts) and content. Creative people share various characteristics across domains, such as imagery, and in particular good imagination, the tendency to think metaphorically, the use of wide categories and images, the preference for non-verbal communications, and the ability to create internal visualizations.

Different approaches can account for the extent to which way creativity benefits from imagery. The first approach relies on the view that imagery is a subjective or phenomenological experience, that cannot be objectively observed. It is only possible to infer other people's imagery by their verbal accounts or behaviours. This approach traditionally focused on the relationships between the self-report vividness of imagery and traditional psychometric measures of creativity, as systematized by divergent thinking. However, it also possible to find studies that correlate vividness of imagery to actual creative behavior and sparsely to attributes of creative products.

The second approach underpins imagery as an independent internal representation and assumes relevance on the basis of its capacity to predict objective performance. On the one hand, it correlates spatial tests to creativity, on the basis of the evidence that spatial tests can also involve the use of imagery. On the other hand, it focuses on the emergent properties of imagery, on

the basis of the experimental evidence that imagery is characterized by properties (perceptual, spatial, and transformational) that support the creative process.

The third approach has been developed within the frame of embodied cognition and conceives imagery as a non-automatic mental simulation that relies on the partial reactivation of past sensorimotor experience (simulation view), or as an ongoing activity that allows the body to interact with its environment (enactive view). The simulation view focuses on imagery as an internal mental representation, whereas the enactive views it as a motor process.

Imagery as a Phenomenological Experience and Creativity

Imagery conceived as a subjective experience is related to vividness and control of mental images. Vividness refers to the ability to form clear and detailed images, associated with the preservation of perceptual information whereas control is the ability to retain images for sufficient time to effect the desired rehearsal, being associated to the voluntary manipulation of images, regardless of their vividness.

Both vividness and control have been hypothesized to be associated with divergent thinking, that is to the ability to produce an open-ended ideational searching of ideas for problems that have no right or wrong answers (e.g., alternative uses task). Divergent thinking represents an indicator of the creative potential rather than of creativity and can be expressed in different forms, such as verbal, visual (see the Torrance Test of Creative Thinking (TTCT), and motor domains (e.g., [Palmiero et al., 2019](#)). Although divergent thinking tasks rely on the use of imagery, for example different scenarios are imagined while finding alternative uses for a common object, or various images are generated while making different drawings starting from given shapes or parallel lines, the extent to which vividness and control of imagery contribute to divergence is unclear. Vividness and control explain only a small part of the total variance of divergent thinking scores (fluency, flexibility and originality), regardless of the form (visual or verbal) of divergent thinking.

The relationship between vividness of imagery and creative behavior is more consistent. People with higher visual art involvement generally show higher vividness scores of visual imagery as compared to individuals with lower visual art involvement or non-artists. This notion is also in line with the evidence that visual artists rely on the object imagery cognitive style, which is supported by pictorial representations of visual stimuli, defined in terms of specific attributes, such as shape, size, color and brightness. Vividness of visual mental imagery has been also associated to functionality of creative objects produced mentally combining visual elements and in domains of knowledge including creative writing and music.

Imagery as an Independent Internal Representation

Imagery is also conceived as a medium by which information about the appearance of perceptual stimuli, events and symbols can be represented and manipulated objectively. This leads to the assumption that imagery is independent from other forms of mental representations (e.g., verbal).

However, the issue of the independence (nature) of mental imagery has been debated. According to the depictive approach ([Kosslyn et al., 2006](#)) visual imagery would function as a modal analogue of visual perception, involving internal picture-like representations. In support of this view, visual images have been found to possess inherent properties of real stimuli, such as spatial extension ([Kosslyn et al., 2006](#)), and to be topographically organized at neural level, allowing the generation of patterns of activation in top-down fashion as compared to visual perception ([Kosslyn and Thompson, 2003](#)). In this vein, visual images can be rotated, scaled, scanned, and inspected as if one is engaged with real objects. Across years, the analogue approach has been extended to other imagery modalities. The neuroimaging techniques confirmed that specific imagery modalities rely on specific neural networks (e.g., neural circuits corresponding to primary or secondary sensory areas and adjacent brain areas).

Nevertheless, the view that imagery has no symbolic independence has also been proposed ([Pylyshyn, 2002](#)). According to this view, imagery is rather an epiphenomena that sub-serves other cognitive processes. Images are descriptive, amodal representations that rely on abstract, propositional-like format. In addition, images are cognitively penetrable by the tacit knowledge of the world. For example, given that individuals know that more time is needed to cover longer distances, they would take more time to mentally scan longer than shorter distances.

With this in mind, the understanding of creativity appears to be more consistent with the idea that imagery has symbolic independence and possesses properties that can lead to new discoveries. Imagery preserves to some extent sensory-motor properties, even though there are also propositional or amodal components that can take part to the creative process. Therefore imagery specifically contributes to creativity in both subjective and objective measures.

Spatial Tests and Creativity

Imagery modelled as an independent internal representation can be associated to creativity as a form of spatial ability, which is a multicomponential dimension that also includes imagery, that is the visual memory factor, that partially overlaps with the general visualization factor ([Carroll, 1993](#)). The visual memory factor involves imagery because it requires individuals to visualize, maintain and manipulate two- or three-dimensional information in the mind's eye as accurately and quickly as possible.

These spatial imagery operations allow the individual to see the same problem from different perspectives, and, therefore, increase possibilities for multiple creative solutions. Nevertheless, the evidence about the relationships between spatial imagery ability and creativity is contradictory.

Emergent Property of Imagery and Creativity

Imagery relies on an independent internal representation that encompasses properties that cannot be readily deduced but can emerge after opportune cognitive operations (e.g. superimposing letters), giving rise to creativity. However, the discovery of emergent properties is obviously not unlimited, given that the individual differences in imagery abilities, complexity of the stimuli, loss of information in the mental images and structural thinking (imagination) not always allow to go beyond the existing knowledge.

Focusing more directly on the creative potential that the emergent properties of imagery can imply, it is necessary to refer to the creative cognition approach, formalized by the Geneplore Model (Finke et al., 1992). This model assumes that creativity emerges through the mental visualization of specific forms, as an ongoing cycle of generative processes (e.g., association, mental synthesis), and exploratory processes (e.g., conceptual interpretation, functional inference). The generative processes are used in the construction of pre-inventive structures, whereas the exploratory processes are used to examine and interpret the pre-inventive structures. The generative and exploratory processes are recursive until a satisfactory invention has been created.

This approach has been operationalized by three tasks. The creative mental synthesis task (Finke et al., 1992), first requires the use of the mind's eye to rotate, change in size and embed the basic elements to construct a pre-inventive form. In the second step individuals have to think of possible applications (uses) of the pre-inventive structure in order to reinterpret it according to the specified conceptual category. During reinterpretation, mental rotation of the whole pre-inventive structure is also possible. The ability to represent pictorial information (vividness) has been found related to functionality of inventions: positively when the task was carried out in one single step, that is, when the object was created with a conceptual category in mind, and negatively when the task was performed in two steps, that is, when the pre-inventive form was created and then interpreted within a specific conceptual category. In addition, transformation imagery abilities and visualization cognitive style have also been associated to originality of objects. This task places more restrictions on the creative process, requiring more goal-directed thinking, and is more associable to scientific creativity. Secondly, the conceptual expansion task (Ward, 1994) allows the shift from existing schemas (e.g., earth animals) to new schemas (e.g., extraterrestrials) in order to expand the basic concept. Individuals are required to use the mind's eye to visualize the original schema of the animal, and to imagine the extraterrestrial living on a planet different from the Earth. Retrieving and representing knowledge at multiple levels of abstraction are associated with higher original extraterrestrials (Ward, 1994). This can be seen as evidence that the use of analogue images formed by information stored in memory prevents conceptual expansion. This task lays less restrictions on the creative process and seems more associable to artistic creativity. Third, the constraining effects of examples with the toy task (Smith et al., 1993) measures the ability to create a toy which does not conform to exemplars that participants are exposed to. This task also requires imagery because participants have to think of the structure of the new toy and visualize possible applications of it. Therefore, imagery plays a key role not only during the generative phase of the pre-inventive structure underlying the creative object, extraterrestrial or toy, but also during the exploratory phase because it serves to contextualize and verify the appropriateness of the idea.

The framework of the creative cognition approach offers a unique opportunity to understand the role of imagery in the creative process. During the creative mental synthesis task combining occurs in imagery, whereas restructuring requires sketching, giving the possibility to inspect and find new interpretations of the initial images. This means that to pursue creativity, for example in design, imagery might be not sufficient; it is necessary to lean on externalizations (sketches) of ideas to overcome design fixation (for a review see Alipour et al., 2018), that is the restriction of the possibility to achieve a creative solution. This is generally true for innovation and art, since inventions (e.g., Kekulé's discovery) and artworks are developed by getting free from the original imagery-based conception, and relying on restructuring processes. In more practical terms, it is possible to assume to some extent that whereas combining of elements and ideas can occur in the generative phase, involving a strong component of imagery, restructuring takes place mostly in the explorative phase, that might be supported also by external aids. This cycle of interacting generative (combining) and exploratory (restructuring) phases continues until a creative idea is revealed, discovered.

Imagery and Embodied Cognition

The embodied cognition approach disregards the notion that cognition relies on abstract symbols, and focuses on the idea that perception is direct and serves to guide actions while the body interacts with its environment (Varela et al., 1991). The sensorimotor capacity of the body offers possibilities (affordances) of interactions with the environment. This means that cognition is grounded in the body and perception and action are inseparable. Basing on these assumptions, the conservative embodied approaches retains the concept of representation (e.g., the simulation view), whereas the fully embodied approaches totally reject it (e.g., the enactive view) (for a review see Palmiero et al., 2019b). Thus, imagery can be conceived as an embodied mental simulation-based representation, or as an embodied action-based process, with implications for creativity.

Imagery as a Mental Simulation and Creativity

Imagery as a mental simulation relies on sensorimotor processes through the reactivation of the same neural regions that are recruited in actual perception (Barsalou, 1999). According to perceptual symbol systems (Barsalou, 1999), selective attention allows to extract schematic representations of perceptual experience, which are subsequently stored in memory to function as modal symbols. Experience allows to integrate different perceptual symbols into a simulator that produces limitless simulations of the percept and implements all cognitive operations. The most of simulations arise spontaneously whereas imagery is a non-automatic simulation of perceptual symbols. Given that different simulations can be produced by the same simulator, experience can be surpassed in many ways.

This means that productivity of automatic and not-automatic (imagery) simulations constitutes an important source of creativity, such as the creative scientific thinking (e.g., the power of analogies). With respect to the depictive approach, that is also based on the notion of mental representation, this view accounts for creativity not in terms of emergent properties but rather as a mental process that is used to simulate results, solutions and alternatives of the creative process.

Imagery as an Ongoing Activity and Creativity

Following the enactive view, perception uses sensory systems in order to actively seek for specific information needed at a specific moment, as a sort of ongoing exploration of the environment. By consequence, an inner generation of a system of meanings by actions and interactions between the organism and the environment would be created. In this vein, imagery is also based on active exploration of the environment almost as during perception. The visuo-spatial recollections of stimuli from long-term memory are not internal spatial representation, but rather are visuospatial behaviours that are guided by overt attention shifts (e.g., eye movements). The peculiarities of the body and the types of interactions with the environment can give rise to different images in terms of phenomenological and functional properties.

The view that imagery relies on active exploration as a sort of allocation of attentional resources is supported by interference and facilitation effects of imagery on perceptual tasks. In practice, attention devoted to the visual images impairs visual perception in mismatch condition (images and percepts do not correspond), whereas they facilitate visual perception in match condition (images and percept do correspond). Studies of motor behavior occurring during imagery also support the enactive approach, such as eye movements in visual imagery, considered as motor processes that occur during active exploration of the environment, or the typical act of sniffing in olfactory imagery, considered as a motor activity that helps to generate images of odours. Yet, motor cortices (e.g., premotor area and/or supplementary cortex) have been found recruited in all mental imagery modalities (Winlove et al., 2018).

The evidence that imagery conceived in enactive terms supports creativity comes from neuroimaging studies that revealed the recruitment of motor cortices during the execution of creative tasks strongly relying on mental imagery (for a meta-analysis see Boccia et al., 2015). For example, the creative mental synthesis task has been found to recruit, amongst other areas, the premotor cortex. More specifically, while designing book cover illustrations the premotor cortex has been found activated during the generation phase and the supplementary motor area during the evaluation phase of ideas. Given that the premotor area is related to object rotations while the supplementary motor area to rotations of the self about an object, it seems that during the visual creative process, the generation of objects is supported by mental rotation processes, whereas the evaluations of the objects implies that the subject imagines him/herself while using the objects for a specific purpose.

Conclusions

Mental imagery is assumed to play a key role in creativity. Different studies addressed the issue of the relationships between imagery and creativity using a variety of approaches, ranging from psychometric methods based on individual differences (vividness and spatial imagery) to cognitive approaches (internal representation). With the advent of the embodied cognition approach the relationships between imagery and creativity has also been conceived in terms of mental simulations and sensorimotor capacities of the body interacting with the environment. In general, although it is not possible to deny that during the creative production of ideas individuals are supported by imagery, the extent to which imagery contributes to creativity has to be still fully disentangled. Vividness and spatial imagery appears to be scarcely correlated to creative performance, whereas the conception of imagery as an independent internal representation that allows the emergence of creativity has produced more convincing results. Interestingly, imagery conceived as a mental simulation that can help to predict results of the creative process also support the creative process. Considering the anecdotal accounts, whereas the Kekule's discovery can be explained as a form of internal mental representation (unconscious) that has allowed to 'see' the structure of the Benzene, Tesla's invention can be explained in terms of mental simulations, that were run to predict results. Finally, imagery as a motor process also seems to explain to some extent the creative process. The general picture is that imagery is a multi-componential construct that supports creativity in multiple fashions according to the task used to express creativity, the domain of knowledge and the individual differences in imagery skills and creativity. Most importantly, in order to move on the understanding of the relationships between imagery and creativity it appears that a wider perspective is necessary: imagery is not only a representational medium that conveys creativity, but is also a mental process that influences creativity. Basing on the idea that mechanisms

underlying vision for action and unconscious visual imagery do overlap (Brogaard and Gatzia, 2017), the view that imagery is a process action-based would also help to better address the unconscious aspects of imagery involved in creativity.

What Is Imagination?

Imagination is a human cognitive capacity involved in the reproduction of images, experiences and thoughts. However, imagination not merely reproduces, but in the imaginative process, the representations of former experiences, thoughts and images are combined into new constructions. Imagination thus involves the transcendence of reality. Imagination might be anticipatory to deal with the future (*What will happen if I solve this task in this way?*), reproductive to process the past (*what would have happened if, I had acted differently?*), or creative to form new original constructions (*what will happen if I combine my knowledge and experiences in new ways?*).

Imagination is a unique human capacity that psychologists often have an ambivalent attitude towards. It is hard to study imagination experimentally at the same time as it is a fascinating capacity that cannot be ignored in social sciences. It plays a role in many complex human functions, such as planning, problem-solving and creativity and often in interaction with rational thinking (not necessarily in contrast with).

Early 20-century theorists, suggested different distinctions between imaginative and realistic thinking. While the psychologist Eugen Bleuler, in 1912, argued that imagination was a relatively sophisticated ability, other scholars, such as Sigmund Freud and Jean Piaget saw it as a primitive process that would dominate the child early on and that would later be subordinated by realistic and logical thought. The term used by Freud, *primary process* in "Formulations regarding two principles of mental functioning" reminds of Piaget's *egocentric thinking*. They both describe the imaginative form of thinking as having a playful, magical, lucid character and being run by the *pleasure principle*, which means that pleasures and wishes are in focus and that this mode of thinking does not adapt itself to reality. Psychoanalytic thinkers asserted that primary process continues throughout the life-span but is accompanied with more realistic thinking from the age of three to four. Realistic thinking will become increasingly important and help children adapt to the *reality principle*, which means that they can find ways of fulfilling their wishes that is acceptable for others, for instance waiting for their turn. Piaget argued, in "Play, Dreams and Imitations in Childhood", that imaginative thinking and pretend play will be more or less substituted by logical thinking and rule play at about the age of seven.

Bleuler's idea has been supported. Bleuler (1912/1951) proposed that the conceiving of alternatives to reality is a sophisticated capacity that is not possible until a more reality-directed thinking has been established, contrary to Freud and Piaget who hypothesized that children started out with imaginative thinking. Moreover, several imagination scholars today, for instance Inge Bretherton and Paul Harris, assert that the imagination must have a function in human life and cannot only be a mal-functional process that should disappear when the child matures. Research studies have provided support that imaginative play fulfils advanced functions that will help children delineating reality as well as practicing different types of human functioning. Marjorie Taylor and Stephanie Carlson (1997) demonstrated that, in for instance play with imaginary companions, children's social ability and understanding of thinking processes are furthered and is likely to lead to better social functioning in the real world (see Play).

In the 1980s, Jerome Bruner developed his theory on the two forms of thought that humans have evolved. The so called *narrative thought* would be closer to imaginative thinking. Bruner (1986) described narrative thought as bursts of images communicated as sequential statements and this form of thinking emerges in fantasies, dreams and memories and in "what if" speculations. The other type is rational thinking (termed *paradigmatic* by Bruner) and is more orderly and logically structured. The two types of thinking

Bruner considered just as important and have different functions, of which narrative thinking strives for lifelikeness and paradigmatic thinking aims towards the truth. Both these modes of thinking are decisive to organize and understand human experiences. In Donald Winnicott's tripartite model (1995), he added a third kind of thinking sphere that combines materials from reality and imagination. This *transitional sphere* depends on children's advancement in handling representation. As a result of this development, children can merge real objects and symbolic content, something which makes it possible for them to invent transitional objects, such as comfort blankets and teddies. Instead of using the parent as the secure base in frightening or insecure situations, children can make use of transitional objects, which may function as comfort by representing parental safety. It means that a real object with the help of imaginative transformation can become something else – an illusion or symbol for security.

Imagination, Reality, and the Illusionistic Sphere

The transitional sphere between reality and imagination was further outlined by Paul Pruyser (1983), who called it the *illusionistic world*. However, it is not merely in childhood that illusions are made use of, for example in pretend play. The illusionistic sphere continues to be important throughout the lifespan. All forms of play belong to the illusionistic world through the players' creation of something in between the real world and the imaginary world. Pruyser maintained that adults also play through the appreciation of fine arts and in various other creative expressions.

Research has found that healthy adults maintain positive illusions in order to function well. Even if self-deception might seem contra-productive at first sight (and certainly excessive self-deception will be), adaptive positive illusions may give people an impetus for growth. Many challenging tasks would never have been completed, had the uphill battle ahead been fully understood. Illusions such as, unrealistic optimism, exaggerated sense of control and individuals' distorted sense of their capacity have made many incredible endeavors come true.

Play and creativity can also have therapeutic qualities both for children and adults, among other things because the illusionistic sphere is a resting place between one's internal and external world. In the lifelong struggle to keep imagination and reality separate, individuals can pause in the illusionistic sphere and play with alternatives to reality or "play with representations", as Inge Bretherton and Marjorie Beeghly (1989) put it in their profound analysis of children's pretend play. This third sphere consists of a kind of imaginative thinking that Pruyser described as tutored imagination, something which arises when imaginative thinking is combined with realistic thinking in a more deliberate process. The imagination world, would then be something more untamed and more spontaneous. In this chapter, however, both the untutored and tutored imaginative thinking will be referred to as imagination. There are many other constructs that are closely related to the concept imagination, of which *fantasy*, *day-dreaming* and *counterfactual thinking* and some others will be discussed briefly.

Constructs Related to Imagination

Fantasy is a product of the imagination, but often refers to imaginary content farther removed from reality, meaning that it is less likely to occur in individuals' real lives. Fantasy can either be pleasant and wishful in content or involve scaring and catastrophic scenarios.

Other sibling concepts to imagination are used in different research fields. Neuropsychological studies of the so called *default-mode activity* is of interest for the knowledge of imagination, even if this activity involves more than merely imaginary processes. The default-mode activity, as discussed by Jessica Andrews-Hanna et al. (2013) and Jonathan Smallwood (2013), refers to the brain activity in individuals at rest and not involved in anything particular. However, when doing nothing, or in default-mode, individuals often overcome the constraints of the present situation by mentally representing some other place, time, or stand-point, something which is a core aspect of imaginative cognition. These internal mentations may include recollections of past experiences and the construction of future scenarios. The terms *task unrelated thought*, *self-generated thought* and *mind wandering* have also been used in neuropsychology to describe default-mode activity. Within other fields, the terms *stream-of consciousness* (in literary analyses of interior monologues) and *daydreaming* also refer to similar processes. In this chapter, all these constructs representing inner states, in which individuals' attention is directed towards their private thoughts and feelings, will be referred to as daydreaming.

Counterfactual thinking is mental representations of alternatives to past actions and events. It is a more deliberate kind of imaginary process than daydreaming and involves thinking about what might have been.

The emerging ability for imaginary and counterfactual thinking begins to develop surprisingly early together with the first attempts to operate in the subjunctive pretend mode ("as if"-acting) and involves the creation of possible and impossible event representations.

Imagination Throughout the Lifespan

The Development of Imagination in Children

Imagination is a human capacity, but has predominantly been associated with children and childhood activities, such as make-belief and sociodramatic play. The first signs of pretense appear as early as the beginning of the second year when children for instance pretend that they are asleep by closing their eyes. Soon, during the third year, children can enact routine family life events, such as going to bed and later they can act out situations that they have only vicariously experienced, such as going to work.

Bretherton and Beeghly described the long process of development before children have fully acquired the ability for more advanced sociodramatic role play, among other things by learning to handle roles, plots and props. Early forms of pretense often only involve a single role, simple plots and realistic props, whereas later forms of sociodramatic play will also include complex role structures, intricate plots and imaginary or less conventional props. Some other interesting features of role play is the development of meta-communication and different stage-management techniques in order to negotiate the content of play with other players. Techniques to direct pretend play are *magicking*, that involves chanting the pretend action (e. g. “stir, stir, stir” when stirring the soup), *storytelling* (“we went to sleep”), that is telling what is happening and *prompting*, referring to the whispering of stage-directions to the other players (“you were still asleep”). There are some necessary developmental steps in order to master the more advanced types of pretend play: Moving away from the present, steering thought processes and distinguishing between reality and fantasy.

Important Developmental Steps

To *move away from the immediate present* is a crucial development. When fully developed it means that individuals are able to overcome the obstacles of the present by mentally simulating another time, place, or view, which will help them, for instance, distance themselves from the real world or create novel things. The first experiences of moving away from the present is simple active recall of something not present. This process involves the ability for representation but the full development will also involve metacognition (see Metacognition). Before developing metacognitive skills, a simple representational ability has to develop, that is object representation, which includes having the understanding that an object (or person) that moves out of sight still exists and can be recalled and represented as an internal image. Then the ability to slightly transform represented objects will develop, e.g. drinking from an empty cup or letting one object substitute another, as when a stick becomes a horse. More advanced pretense demands a more consolidated representational system, for instance substitution, in which something with a conventional function (e.g., a book) can represent something totally different (a pillow) can only be performed by older preschoolers. Older children will have more advanced abilities at steering their imaginary process, in this case to suppress the conventional function of an object.

The *ability to steer the thought processes* purposefully to some extent involves executive functioning, meaning the control and regulation of actions and cognition performed by the prefrontal cortex. Some basic awareness of thinking – metacognition – is necessary to be able to deliberately switch between realistic thinking and imaginary and also to remain focused on a task (see Metacognition). Task-focus demands regulatory functions to not get distracted by irrelevant internal or external stimuli. Research by Johannes Golchert et al. (2017) indicated that daydreaming can also be more or less regulated. The deliberate form of daydreaming is more related to individuals’ intentions and involves not only default-mode activity but also integration with prefrontal brain areas, whereas the more uncontrolled spontaneous daydreaming do not demonstrate the same prefrontal activation. So the development of imagination and the ability to use the capacity intentionally will demand some form of integration between the default-mode network and prefrontal areas.

The development of the ability to *distinguish between reality and fantasy* is another important step for acquiring imagination, and many scholars, for instance Bretherton and Beeghly (1989), argue that it is practiced through make-believe and sociodramatic play in childhood. When socio-dramatic play involves the immersion into a fantasy world together with others, children need to simultaneously direct the play. Metacommunication with the other players means going out of the play sphere and in the real sphere giving stage directions, for instance: “now the heroine was hungry, so she took an apple from a tree.” Then when acting it out after having switched back into the role character in the play world, pretending to eat the apple by letting a ball be a substitute for the apple.

The development of metacognitive capacity is involved in the process of teasing apart imagination and reality, individuals’ separation of their own beliefs and others’ experiences, and the awareness of their own thinking and their imaginary processes.

However, even if the ability to distinguish between reality and imagination has been acquired, situations also occur when there is a blurred line between real and pretend actions. For young children, emotionally loaded pretend content, can become “too real”, for instance when a parent enacts a monster, the child may become actually scared. For adults too, fictional presentations can evoke strong feelings, indicating that the spheres are never fully detached. The real world also intrudes into the play world at times. If an additional child wants to join the play, new roles will need to be invented to suit the new number of players and if someone falls and gets wounded, the plot might be changed to include a visit to a herb woman who can heal the wound.

Modelling the World Through Pretend Play

Why is the development of imagination important for children? In the pretend play world, children deal with their experiences by creating model situations and they learn to master reality by experimenting in the play world. Children both relive experiences and make up alternatives to reality in make-belief play and through this activity, they have eventually built a useful representational model of their world, which helps them handling their everyday reality. In interviews with 26 children, Hoff (2013) found several functions of imaginary friends. Children used their imaginary companions as inner mentors and more specifically the make-believe friends helped the children feel less lonely and motivated the children to do scary or difficult things. The imaginary friends thus served as symbols for company, comfort, and encouragement. Some children also reported having imaginary companions of opposite characters to themselves, which seemed to support an experimentation with alternative selves that might assist children’s identity development.

However, having established a firm grip on reality, does not mean that the ability to transform and reinvent reality in imaginary processes disappears. Imagination will continue into adult life in the form of daydreams, cultural appreciations and, for some individuals, professional works of art. In fact, as suggested by Bretherton and Beeghly, the goals of authors and playwrights resemble

objectives pursued by children in their pretend worlds. Several famous authors, such as the Brontë sisters, created elaborated imaginary worlds as children. An imaginary world involves a long-lasting elaboration and development of a pretend space, with which the child is consistent over time concerning its contents, such as its imaginary people, places and artefacts. The imaginary world matters to the child and is something the child takes pride in. Such childhood imaginary experiences often serve as inspiration for adult artists' work.

Adult Imagination

Imagination is not merely a childhood activity, but rather an essential part of many adult capacities, such as in the preparation of new tasks, in making choices between different possible roads by simulating different outcomes, but also in the combination of various knowledge and experiences into new ways of solving problems. Also, in situations when there is no immediate use for the imagination, it can function as entertainment in order to bear a tedious task.

Recent research suggests that the default-mode network and its subsystems, that provide the substrate for day-dreaming, consumes a majority of the brain's energy. In his research studies, [Eric Klinger \(2013\)](#) had his participants estimate the percentage of waking thought that was daydream-like and they reported about 30%–50%. Klinger suggested that this capacity has evolutionary reasons to exist, that it must have benefits for the species survival.

There are, however, also costs. Research studies indicate that adaptive and maladaptive manifestations of daydreaming varies broadly across individuals. Several mental health disorders include problems arising from daydreaming. Not only the content of daydreaming and its relations to well-being are different, but also the amount and control of imaginative thought varies across individuals. Even if an average person spends up to half their waking time daydreaming, there are also groups of people, for whom the imagination is totally lacking and individuals with psychiatric illnesses, for whom the line between reality and imagination is vague and whose inability to distinguish what is real and what is intruding imaginary content is a defining symptom.

Fantasy Proneness and Uncontrolled Imagination

There is great variation in how much people use their imagination. [Judith Rhue and Stephen Lynn \(1987\)](#) explored extreme fantasizers in the normal population, and termed the personality syndrome *fantasy proneness*. Fantasy proneness means a deep long-lasting involvement in imagination and their sample of college students represented the upper 3% on an imagination scale.

The fantasizers were compared with low-fantasizers (lower 3% of the same scale). There are at least two roads, from which high fantasy involvement develops. For some fantasizers, the imagination involvement is life embellishment inspired by highly fantasy-involved role models and for others, it is a form of coping with traumatic events or an aversive environment. The fantasizers told about parental encouragement for fantasy involvement and engagement in cultural activities, but only the encouragement to read stories discriminated fantasizers from low-fantasizers.

Childhoods of fantasy-prone individuals more often contained loneliness and also abuse compared with low-fantasizers. However, at the same time as the fantasizers reported more physical punishment, they also described a greater use of imagination to cope with the pain. Despite reports of abuse, the fantasizers assessed their home environment as positively as the low-fantasizers. Lynn and Rhue suggested that fantasy may serve a functional role in maintaining a positive view of the family.

Fantasizing may also serve other adaptive and compensatory functions in relation to the individuals' reports of loneliness. More of the fantasy-prone individuals asserted that they preferred solitary play over play with friends compared with the low-fantasizers. Despite these distinct childhood patterns, the high and low group were equal on measures for psychological well-being, social adjustment and college performance. In adulthood, the rich imagination of the fantasy-prone individuals seemed to function as escape from the constraints of reality, as a channel to handle anger, and to regulate other emotions.

There are also variation in how much control individuals have over their imaginary processes. Recent research by [Golchert et al. \(2017\)](#), compared spontaneous daydreamers with deliberate daydreamers. Spontaneous daydreamers reported attention deficits more frequently and reacted more to their internal experiences. The deliberate daydreamers modulated their daydreaming in relation to if they were involved in easy or demanding tasks. When involved in easy tasks, the individuals could afford daydreaming without performance costs and therefore engage in daydreaming, but in challenging tasks they constrained their thinking in order to concentrate on the external task.

There are also pathologic mental disorders that are related to uncontrolled imagination, such as dissociation and schizophrenia. In these disorders, the diagnosed individuals no longer have the ability to distinguish what is a product of their imagination and what is real.

Dissociation means that an individual detaches from their experiences, predominantly as a way to handle conflicts or adversities. In severe cases, the detachment is so complete that the individual has different personalities for different experiences and cannot merge these into one coherent self.

[Kathryn Becker-Blease \(2013\)](#) distinguished between pathological dissociation and non-pathological dissociation. The non-pathological dissociation is also referred to as absorption or just fantasy proneness. Pathological dissociation often develops from normal childhood imaginative and dissociative processes but due to a history of child abuse becomes a maladaptive coping style.

Moreover, pathological dissociation includes memory disturbances, distorted perception and confused identity, so that individuals who suffer from it may have difficulties remembering significant events, such as their wedding, and may not be able to recognize themselves in the mirror. The line between pathological and non-pathological dissociation is, however, not always clear as

people with non-pathological dissociation are deeply involved in their imagination and to some extent may live in an imaginary world of their own, partly because of an inability to cope with reality. There are also creative people who make use of their imagination and dissociation in productive ways in their work who show similar symptoms as those diagnosed with pathological dissociation. However, Becker-Blase identified some discrete signs of pathology, which include that an individual has several different personality states that are experienced as distinct with separate memories that only can be accessed during one of the states, and that the individual is not able to move between these states deliberately.

In schizophrenia, individuals have lost the sense of reality, which means that the line between reality and imagination is confused (just like with other less long-lasting psychotic illnesses). Together with reality distortion, individuals with schizophrenia often experience dissociation; and have a history of trauma, of being bullied or abused, or of social adversity. These antecedents are often part of the cause for the illness in interaction with genetic factors. Schizophrenia symptoms include hearing voices (and other hallucinations), believing in delusions and paranoid thinking, speaking in ways that is difficult for others to follow (termed *thought disturbances*) as well as so called *negative symptoms*, which includes emotional withdrawal and apathy (see Schizotypy).

Both dissociation disorder and schizophrenia are examples of when the imaginative capacity cannot be used adaptively, because the imaginative contents become as real as the objective world and the individuals react to internal and external stimuli with no ability to differentiate between them. However, there are not just people with uncontrollable imagination but also those that suffer from impoverished imagination.

Lack of Imagination

Different people will have different levels of imagination, and for some individuals, the imaginative capacity is constrained. For some, it depends on environmental reasons and for others, disorders or injuries led to reduced imagination.

There are children growing up in socially disadvantaged environments but also those from families that discourage fantasy-involvement who may suffer from impoverished imagination. However, research found that play therapy can be used to train the imaginative ability. In her seminal study, Sara Smilansky (1968) showed that a nine-week socio-dramatic play intervention could improve children's ability for role playing. The study compared 800 children divided in experimental and control groups. The children came from both advantaged and disadvantaged backgrounds, and both groups demonstrated benefits from the intervention. For some individuals, the imaginative deficits were more enduring.

One of the diagnostic criteria for autism spectrum disorder is that the individuals find imaginative processes challenging. People suffering from autism spectrum disorder has been found to have default-mode network dysfunctions, something which seems to be part of explaining their deficits in social functioning. The default-mode network is also essential for meta-cognition, the capacity necessary to think about thinking and for understanding other people's mental states. Metacognition is also necessary for making up alternatives to reality in the imagination. However, the basic representational ability is not impaired in individuals with autism compared to typically developed individuals. Fiona Scott et al. (2013) in their research demonstrated that it is only the ability to form non-veridical images in their mind that appears to be impaired for individuals with autism. Individuals with autism also demonstrate significantly less pretend play (and also creativity) in comparison with either typically developed children or controls with Down syndrome.

The Role of Imagination in Human Functioning

Functions, Benefits, and Costs of Imagination

Because the default-mode network consumes a great amount of the brain energy, it has been suggested that this kind of processing serves important human functions. Some of the suggested functions of imagination involve its capacity to overcoming constraints, such as in planning future events and finding new and useful alternatives for action. Klinger also argued that direct or indirect daydreaming will be involved in successful goal-pursuit. Increased activation of daydreaming will occur when circumstances are unfavorable for goal-fulfilment, and then the daydreaming may relate to goals. When individuals are involved in external activities that are relevant for their goal-pursuit, daydreaming is typically reduced.

Another essential function of imagination is that it promotes creativity. There is also research demonstrating that imaginative people are better at delayed-gratification, meaning being able to wait longer for a reward. Moreover, a function of "off-line" imaginative thinking is that it appears to support memory consolidation, similar to what takes place during sleep, though the memory consolidation in daydreaming is not as efficient as in sleep (Klinger, 2013).

Imaginative processes can have different qualities that will influence individuals in various ways. Daydreams can be temporary flights from reality providing relaxation or being experienced as joyful for the individual. Daydreaming can also be experienced as frightening and compelling. There is a relationship between daydreaming content and mood as Andrews-Hanna et al. (2013) explored. Repetitive thinking of negative events, so called ruminations constitute a form of negative daydreaming that is linked to negative mood and depression. Negative moods influences thinking toward the processing of past events. It appears to be a vicious circle, in which ruminations produce more negative mood, which in its turn leads to even more thinking of the past. Negative daydreaming is characterized by being experienced as personally significant and is at the same time more abstract with fewer details. On the other hand, future-oriented thoughts are experienced as more positive. Andrews-Hanna found that reports of positive daydreaming content was associated with emotional health and wellbeing. Positive daydreams are characterized by more concrete details but are not as long-lasting nor self-focused as negative daydreams.

In a study with children, Hoff et al. (2019) found a link between positive fantasy contents for example, vivid and happy daydreams, and intrinsic mastery motivation, whereas negative fantasy content was associated with more externally driven avoidance motivation. Examples of negative fantasy content was scary daydreams and fantasies about monsters.

Thus, the content of fantasy and other imaginary processes seems to be decisive for different individual outcomes. Individuals who are able to regulate their imaginative thinking to include predominantly positive or productive content will be more likely to make the imaginary capacity function adaptively.

There are situations, in which attentional lapses in the form of daydreaming are not beneficial. It may concern reading, learning and the performance of other challenging tasks, which are activities demanding individuals to attend to the external world for a sustained period of time.

Nevertheless, for most individuals imaginative processes occur now and then. For individuals with poor metacognitive skills, such as those suffering from attention deficits, intruding internal thoughts (as well as external stimuli) are extremely difficult to regulate and this will lead to frequent task failure. At the same time, learning and working with demanding tasks often require an integration of information from the external environment with internal representations, for instance the retrieving of memories might support performance. It means that, some form of deliberate guidance of the imaginative content in goal-relevant lines may help successful task performance. In creativity tasks, the integration and flexible use of different kinds of thought (rational and imaginative) is essential.

The Relation Between Imagination and Creativity

Laypeople often mix up imagination with creativity and see the constructs as interchangeable. However, creativity refers to a capacity needed to achieve a product or idea that is both unusual and useful. In contrast, imaginative processes do not need to be unusual nor useful, even if they can be. Nevertheless, imagination can be described as a necessary part of the creative process. In the reflection and inspiration phase of the creative process, also termed the incubation phase, imagination is the most essential cognitive capacity, enabling broad inclusive thinking, whereas in other creative phases, such as in the realization and in the evaluation phase more focused and rational thinking is demanded (see Incubation, this volume).

Recent neuro-research pointed out that the integration of default-mode activity (thinking at rest) with more controlled functioning is important in order to spark creative insights. This deliberate daydreaming is decisive for instance, to achieve meaningful memory retrievals, which support the creative process. In fact, the psychodynamic researchers that the chapter started out with also asserted that creativity constituted an interplay between primary and secondary process thinking.

Thus, research implies a necessary *regulated flexibility* of the imaginative process in order to support creativity. It can be related to a discussion in the creativity field whether creativity is dependent on controlled or disinhibited cognition. Several creativity researchers have stressed disinhibition in order to reach the associations furthest away from the conventional answers. It could be exemplified by a divergent thinking task, in which participants are asked to give as many suggestions of how to use an empty milk carton. "Having things in it" will be produced early by most individuals and does not require much disinhibition, whereas "filling it with sand and use it as a doorstep" will be a later (more remote) suggestion and demands more imaginary disinhibited thinking (See Associative Theory).

Other scholars have described creativity as a combination of *variation* and *selective retention*, meaning that first, a more inspirational free-floating thinking (imaginative) will produce a number of new ideas. Then secondly, a more rational, possibly criteria-based, decision process will be necessary in order to make a choice between all the generated ideas. This selection process leads to the actualization and completion of the creative work, but is less dependent on imagination.

Apart from the widening process (divergent thinking), there are other kinds of creative process, such as combining, and restructuring. None of these processes would work without the integration of imagination with more logical thinking. In *widening processes*, as the milk carton task, regulated flexibility of different thinking modes will be necessary for the integration of expansive thinking in order to produce many unusual solutions (door stop), and cognitive control to reduce too disinhibited, deranged associations (see Divergent Thinking). *Combinatory processes* can be exemplified by a picture completion task, in which participants are asked to link given fragments and to produce their own original designs. This task also demands both the capacity to produce and follow spontaneous inkings as well as to constrain the process in order to reach an end "product", which means finishing the picture in a way that makes sense to others.

Finally, *restructuring processes* are used in so called insight problems. One example is the candle task, in which participants are given a candle, a box of thumbtacks and a matchbook and are asked to fixate and light the candle on a wall in a way so the wax does not drip on a table. Also, in this task, the integration of different thinking modes are decisive. First, disinhibited more exploratory imaginative thinking is necessary for participants to distance themselves from the immediate associate (sticking the candle to the wall with the tack) and to find other ways, such as the correct solution, which involves emptying the tack box and nailing it to the wall and then using the box as a candle holder. After having managed to restructure their thinking and overcome the functional fixation about the box as not just a container for the tacks, participants then are obliged to use more restrained thinking to finalize the task (see Insight).

Concluding Comments

Imagination research is prominent in many different fields, such as developmental and educational psychology, which investigate pretend play and sociodramatic play as well as imagination and its links to reading, learning and motivation. Moreover, research

within the field of neuropsychology expands the knowledge concerning brain functioning supporting the production of imagination and the research on the default-mode network is an interesting road. Within personality psychology and clinical psychology, individual differences are explored to understand what antecedents underlie the development of fantasy-proneness or impoverished imagination. No matter in what field imagination scholars work, there is a depth of knowledge to unravel concerning functions, relations, and benefits as well as costs of the imagination.

Introduction

Scientific theories have been constructed through multiple studies that are based on collecting and analyzing data. Because good scientific theories are articulated in ways that are testable and replicable, they are referred to as explicit theories. Over seven decades, creativity has been explored and explained through several kinds of explicit theories. Creativity has been psychometrically measured as part of *Structure of Intellect* (Guilford, 1967) and defined in terms of personality traits. Theories of cognitive processes underlying creativity were proposed and tested. Social psychology theories attempt to explain how people are facilitated by or interact with environmental factors to be creative. However, explicit theories do not perfectly characterize how people behave and make choices to be creative, despite the well-grounded evidence accumulated in scientific research.

In fact, people's personal beliefs about creativity affect their opinions and expectations of themselves and others. The naive beliefs about creativity held by "lay people" (those who do not scientifically study creativity) are referred to as implicit theories. These are merely personal and are not necessarily empirically tested. Implicit theories are as important as explicit theories because uncovering implicit theories helps to understand common-cultural views of particular groups reflecting their cultural and demographic values. Also, scientists with implicit theories may use these to guide their research of explicit theories. More importantly, people make judgments of creativity, adjust expectations of creativity in themselves as well as others, and even make decisions to be creative corresponding to their implicit theories. For instance, people put less effort into being creative if they believe creativity is innate and stable over time. Also, if people believe that artistic talent is a main component of creativity, they should enhance their artistic talent to be creative. The roles of implicit theories are critical when involved in the selection and placement of students. For instance, if teachers believe children who are good at drawing are more creative, they would allocate resources to enhance artistic experiences in the class. Similarly, if managers believe creativity is simply a different form of intelligence, they would recruit bright employees and expect them to be innovative in their work.

This entry reviews four topics: a) history of empirical research about implicit theories, b) misconceptions and the intricate nature of implicit theories, c) cultural differences, and d) methods to be used in implicit theory research which are followed by e) discussing three challenges and related opportunities.

History of Empirical Research About Implicit Theories

Since Torrance investigated teachers' beliefs about creative children in his seminal work in the early 1960s, implicit theories of creativity have been studied in various populations: teachers, parents, children, artists, scientists, college students, professionals, adults, and many other groups.

What Do Implicit Theories Look Like?

Among many populations, teachers have constantly received the most attention when examining implicit beliefs of creativity. It is not surprising given the major role that teachers play in identifying children's creative potential and making decisions in various educational settings. Among the approximately 39 studies about implicit theories found from 1963 to present in creativity

research, teachers' beliefs about creativity were investigated in 72% ($n = 28$) of the identified studies. Since the late 80s, parents' implicit theories (e.g., [Runco, 1989](#)) emerged in creativity research. Parents are as important as teachers in making decisions about children's educational placement. They are also equipped with the perspectives encompassing children's cognitive as well as social/emotional development in contexts beyond the classroom. In fact, [Runco \(1989\)](#) found that teachers' implicit theories of creativity focus on intellectual traits and that the perceived intellectual traits are highly related to their perception of motivational and attitudinal traits in children. The strong tie between creativity and intellectual traits in teachers' implicit theories was also demonstrated by high correlations between children's intelligence test scores and ratings by teachers ($r = 0.34-0.66$). In contrast, parents' implicit theories were marginally correlated ($r = 0.04-0.36$) to teachers' implicit theories and less dependent on intellectual traits. This is found in that none of attitudinal and motivational traits were significantly correlated with children's intelligence test scores. The differences were anticipated as parents and teachers are often unlike in their expectations for and experiences with children.

Although children themselves are the other important agent in making decisions regarding their educational opportunities, it was only later that children's implicit theories became a research focus (e.g., [Saunders Wickes and Ward, 2006](#)). [Saunders Wickes and Ward \(2006\)](#) found that gifted adolescents believed artistic talents, popularity, and questioning to be characteristics of creative people when they were asked to rate creativity in created profiles. Artistic talents were consistently reported when average and younger children were asked to define creativity. However, gifted adolescents seemed to apply different rules when they judged their own creativity believing that risk-taking, awkwardness, intellect, and impulsiveness were characteristics of creative people ([Saunders Wickes and Ward, 2006](#)).

What Factors Affect Formulation of Implicit Theories?

As described in the studies above, illustrating implicit theories helps us to more deeply understand what people's beliefs look like, but they do not necessarily explain why people choose to behave in certain ways. Recent research tends to focus on investigating to which factor people's implicit theories are attributed and how people's implicit theories are translated into their decisions about themselves and others. Still, teachers are targeted as the population of interest (e.g., [Gralewski and Karwowski, 2016](#); [Karwowski, 2007](#); [Paek and Sumners, 2017](#)). For instance, [Karwowski \(2007\)](#) found that teacher nomination of creative children is largely attributed to students' academic achievement and, therefore, is not necessarily indicative of children's creative potential. Teacher nomination is a subjective method of identification largely based on teachers' implicit theories of creativity. Thus, the finding implies that teachers' implicit theories of creativity may be partly confounded with their notion of good students. This finding was repeatedly affirmed in the previous literature ([Bachtold, 1974](#)). The misled implicit theories in teachers should be underlined because they potentially cut down the accuracy of recognizing students' creative potential ([Gralewski and Karwowski, 2016](#)).

How Do Implicit Theories Impact Identification and Development of Creativity?

Lately, practical impacts of implicit theories in teachers seem to drive research toward emphasizing probable consequences of teachers' implicit theories, going beyond describing what teachers' implicit theories look like. For instance, [Gralewski and Karwowski \(2016\)](#) conducted an explorative study classifying teachers into four groups based on their beliefs about creativity. They found that at least one-third (34%) of teachers hold implicit theories of creativity that failed to predict students' actual creativity. In other words, their implicit theories are not aligned with whom creative students really are. For instance, they rated key attributes of creative people, such as inventiveness, problem solving, and openness, all low. Their ratings imply the probable misconceptions that teachers hold about creative students. [Gralewski and Karwowski](#) also identified two other groups of teachers. One group consisted of teachers (19.8%) who perceived creativity as adaptive, valuing perseverance in addition to inventiveness and openness. The other group consisted of teachers (45.8%) who perceived creativity as more innovative and radical. Surprisingly, what teachers believed about creativity indeed affected their assessment of students' creativity. For instance, teachers tended to accurately assess creativity only in females if they perceived a creative student as an adaptor, while teachers tended to accurately assess creativity only in males if they perceived a creative student as an innovator. Put differently, teachers' gendered beliefs affect how they assess creative potential in students. Although their finding is tested in only 131 teachers, implying the lack of generalizability of the finding, it has been repeatedly affirmed that teachers' implicit theories of creativity may overlook students who may not match their prototype of creative students. More importantly, this oversight may disadvantage certain groups.

Teachers' implicit theories are determined by behavioral and academic functioning at school through achievement, friendliness, and discipline. The implicit theories may even vary by gender of students. If teachers' ratings of student creativity are derived from students' actual creativity, then teacher ratings of creativity in students should be highly correlated with students' actual creativity. Interestingly, teachers' creativity ratings reflect students' actual creativity only in boys but not in girls. This gendered difference implies that teachers tend to construe boys as creative and girls just as polite. Students' gender is one of many factors affecting teachers' implicit theories possibly producing disparity by groups in talent identification. Teachers' inaccurate implicit theories of creativity may be a concern particularly when students internalize these beliefs about creativity through their daily interaction with teachers in the class.

Misconceptions and Intricate Implicit Theories

Teachers' implicit theories specific to certain groups also appear in students with special attributes. Teachers tend to endorse that only select students can be creative (Aljughaiman and Mowrer-Reynolds, 2005). They believe creativity to be attributed to intellectual characteristics such as cleverness and intelligence and artistic attributes such as awareness of beauty and aesthetic products. In fact, high intelligence and artistic ability do not guarantee creativity as documented in the literature (Kim, 2008). This misalignment is not surprising as the discrepancy is well-documented between teachers' implicit theories about creativity and the attributes that creative children actually exhibit.

The discrepancy between implicit and explicit theories are often defined as misconceptions (Paek and Sumners, 2017; Paek et al., 2019). Teachers tend to show more misconceptions about personality characteristics of creative children. More specifically, Paek et al. (2019) found that it seemed difficult for teachers to tell what characteristics were not really indicative of creative children. This misconception tended to be apparent if the characteristics (i.e., sincere, honest, & well-mannered) were desirable in the classroom. Interestingly, these personality characteristics are not necessarily noticeable in creative people even when findings from 13,167 people across 83 studies were synthesized in Feist's (1998) meta-analysis. His synthesis indicated that creative people were more likely to be open to new experiences and flexible; more ambitious and impulsive; and more self-confident and hostile. Additionally, creative people were more likely to be anxious and emotional although these characteristics were specific to artists. In other words, teachers' prototypes of creative children may not necessarily match people who are actually creative, indicating teachers' probable misconceptions. Teachers' prototypes of creative children, and favoring ideal students, are repeatedly upheld in the literature (Bachtold, 1974; Paek et al., 2019). The prototypes may explain teachers' expectations for creative children to be curious, self-confident, or sincere but not to always ask questions, be naughty, or critical (Bachtold, 1974). As seen in the teachers' expectations, teachers may hold conflicting beliefs.

It is pretty unique to implicit theories of creativity that people, markedly teachers, simultaneously hold conflicting beliefs about creativity or creative children. Put differently, the conflicts imply a complexity and intricate nature of teachers' belief systems about creativity. The conflicting beliefs may explain why teachers use different standards for creative children. For instance, teachers tend to nominate ideal students (Gralewski and Karwowski, 2016; Karwowski, 2007) as creative, while they tend to use negative descriptors to describe creative children they have taught (Bachtold, 1974).

Conflicts are also found when teachers are asked about their beliefs of the nature of creativity. Paek and Sumners (2017) found that teachers simultaneously hold fixed and growth mindset toward creativity, in contrast to that people have either a fixed or a growth mindset regarding intelligence. Teachers are not the exception, because randomly selected adults simultaneously tend to hold both mindsets, too. Creative mindset refers to whether teachers believe creativity to be a fixed or changeable (i.e., growth) characteristic. Put differently, teachers tend to believe creativity is an innate talent if they believe that creativity is fixed. Thus, they are likely to believe that only those who have special talents (e.g., giftedness, high IQ, or artistic talents) can be creative (Aljughaiman and Mowrer-Reynolds, 2005). On the other hand, teachers tend to believe that creativity can be taught or developed over time if they believe that creativity is changeable. They are, in turn, likely to believe that everyone has the potential to be creative. Teachers' beliefs about creativity, in fact, impact their confidence in teaching for creativity. Stated simply, if teachers believe creativity is attributed to innate talents, teachers are less likely to believe that all children have potential to be creative. The more teachers believe that not all children have creative potential, the less likely they are to be optimistic about their ability to teach for creativity. This probable cause-and-effect chain was empirically examined by Paek and Sumners (2017).

Teachers' notions that children can develop their creativity over time may be contingent upon whether the children innately have special talents. This conditional notion appears to be a conflict in their beliefs. The notion also explains conflicts in how confident teachers perceive themselves as teaching for creativity: Teachers value children's creative potential but tend not to believe that they were able to teach for creativity. Similarly, Aljughaiman and Mowrer-Reynolds (2005) found that teachers feel pretty confident in teaching creativity but not in all students. Simply put, teachers believe that creativity can be taught by special teachers in select students, but not by themselves as well as not in all students.

Cultural Differences

Implicit theories reflect unique values of particular groups, as evident by similarities and distinctions in what they believe about creativity by groups (teachers vs. parents, regular students vs. gifted students). The group-specific values matter because implicit theories promote or inhibit creative behaviors mediated through value systems. Communities sharing different values, from demographic groups to cultures, are likely to hold different beliefs about creativity. Correspondingly, culture-specific implicit values may determine whether creative behaviors are encouraged and, specifically, what types of creative behaviors are encouraged. Research has grown in examining and comparing implicit theories specific to cultures since the early 2000s (e.g., Paletz and Peng, 2008) and continued recently (e.g., Paletz et al., 2011).

Paletz et al. (2011) tested the hypothesis that creativity is expressed differently in Eastern and Western cultures. Indeed, the results confirmed that cultural differences on individual foci versus collective foci were repeatedly found in the previous literature. In their study (Paletz et al., 2011), East Asians were more likely to perceive visible and interactive activities or traits (e.g., social interaction, sports, cooperation, extraversion) in social settings as creative, whereas Caucasians were more likely to perceive internal activities and traits (e.g., thinking, designing, intelligence, depression) and internal professions (e.g., artist, philosopher, and

spiritual person) as creative. This finding implies that Asians would portray a creative prototype as more externally sensitive/active. This may be explained by the generalization that Asians value and are more sensitized to social relationships and social impacts of creative outcomes. However, implicit theories are not always contrasting between Eastern versus Western cultures. [Paletz and Peng \(2008\)](#) attempted to test cultural differences in perceiving novelty and appropriateness when judging creativity of products. Novelty, which is known as a main component of creativity, obtained consensus across three countries (i.e., China, Japan, and United States). Another finding was contrasted to the common notion that Americans would not value appropriateness as much as they did for novelty; when appropriateness of products was manipulated, Americans' ratings on creativity of products were affected as much as they were in Japanese. Yet, Chinese's ratings were less affected by manipulating appropriateness. A single common theme may not simply explain all cultural differences in implicit theories partly because creativity is multidimensional and complex by nature. Culture-specific implicit theories are even more complex to study, as collective values may keep changing through interaction with cultural tradition along with societal changes.

Methods of Implicit Theory Research

Implicit theories are complicated and complex by their nature and consequently require the use of various methodological approaches: qualitative, quantitative, and even mixed depending upon the purpose of research.

Self-Report Open-Ended Questionnaires

Implicit theories cannot be uncovered unless "lay people" are directly asked about what they believe about creativity in their own words. The nature of research on implicit theories has driven researchers to describe the common themes arising from the interviews or open-ended questionnaires. Furthermore, an ethnographical approach has sometimes been taken to delve into teachers' perceptions about classroom environment facilitating children's creativity. Merely describing teachers' and parents' words indeed uncovers what they think but does not necessarily show which thoughts are more or less prevalent.

The summary and synthesis can be done in many different ways, not only qualitatively but also quantitatively. Quantifying the themes may help with counts, percentages, and ranks. When responses in open-ended or semi-structured questionnaires are counted and ranked, it is easier to see what thoughts are dominantly found in individual groups and even compare them across groups ([Aljughaiman and Reynolds, 2005](#)). Research documented on this topic has been used to construct instruments measuring implicit theories such as Adjectives Checklists of Creative People as found in many studies (e.g., [Karwowski, 2007, 2010](#); [Paek et al., 2019](#)).

Social Validation

Another interesting method is social validation ([Runco, 1989](#)). If we aim to diagnose and/or identify children with special needs, we might like to count on those who have plenty of experience with the children, no matter how much scientific knowledge they have about special needs. This technique is referred to as social validation ([Schreibman et al., 1981](#)). For instance, parents or undergraduate students with no training in special education are able to tell whether autistic children improved their behaviors before and after behavior therapy as much as trained judges ([Schreibman et al., 1981](#)). Schreibman et al. underline the social importance of treatment effects in autistic children. In other words, subjective ratings collectively done by naïve judges are as important as objective ratings by experts although their scientific knowledge is far different by its scope and depth. When it comes to social importance, creativity is not an exception. Significant others, such as parents and teachers, who have spent a substantially large amount of time with children may be more able to tell the social importance of creative potential that children exhibit, although their judgment may not be entirely corresponding to what has been scientifically affirmed.

Social validation has been commonly used in examining parents' and teachers' perceptions of creativity and creative children. Two phases are typically taken in the social validation methodology ([Runco, 1989](#)). In the first phase, teachers and parents are asked to define or illustrate creativity. Their responses are qualitatively described, or the frequency of words (or phrases) appeared in their responses are simply counted. Then, the summarized responses are used to construct a structured instrument to be used in the target groups. In the second phase, the instrument constructed in the first phase is further used in collecting quantitative ratings about creativity in other samples of the target groups (e.g., teachers or parents).

Advanced Analyses for Inferential Statistics

Beyond describing what teachers believe about creativity, research has employed inferential statistics ranging from regression analyses to item response theory. Regression analysis was performed to see what factors affected teachers' nomination of creative children ([Karwowski, 2007](#)). The results indicated that students' academic achievement was the main predictor, and students' creative attitudes and actual performance in a creativity test were not. Furthermore, confirmatory factor analysis was examined to identify latent factors underlying teachers' ratings of adjective checklists ([Karwowski, 2010](#)). It was confirmed that teachers' belief of personality characteristics exhibited in creative children consisted of five factors (i.e., dynamism, intellect, excitability, agreeableness, and conscientiousness). Further, the five factors were compared between creative and "well-behaved" students indicating that teachers

perceived creative students as more dynamic, intellectual, and excitable while less agreeable and conscientious compared to good students.

Personality characteristics were analyzed even at the item level using a Rasch analysis (Paek et al., 2019): The results indicated that teachers tended to show more misconceptions determining what are not the characteristics of creative students. This misconception was apparent when the characteristics were desired in the classrooms. More sophisticated factor-analytic techniques were further employed in this line of research. For instance, teachers were classified into four groups based on their beliefs on the six factors of personality characteristics of creative students using latent class analysis (Gralewski and Karwowski, 2016). The identified groups were further compared to see if they were different in their accuracy in assessing students' creativity. The consequences of teachers' beliefs of creativity in students was also tested in a moderated mediation model (Paek and Summers, 2017). Given the intricate nature of implicit theories about creativity, researchers need to continue to develop and use solid experimental design as well as innovative methodology in future research.

Challenges and Opportunities

In this section, challenges and opportunities are discussed. First, implicit theories have a long history encompassing many studies, which reveal that some implicit theories correspond to explicit theories, while many do not. Thus, it is of great interest how scientifically untested beliefs affect how people behave and make decisions in regard to being creative. This causal link has plenty of implications in helping people to correct their misconceptions and improve their daily practice to be creative. The majority of research asserts the probable impact of or mechanism underlying implicit theories based on self-report survey designs. This can be further tested in more rigorous ways including laboratory experiments. In many cases, it is challenging to study implicit theories because of its intricate nature, demonstrated by how many conflicting beliefs are entangled and interplay with one another. Given this intricate nature of implicit theories, conventional methodologies may not be able to fully discover how the beliefs are connected, interplay with one another, and even affect the way in which people behave. Thus, various methodologies quantifying people's beliefs and how they interplay are needed to extricate the complicated beliefs beyond simply illustrating or counting them.

No matter whether implicit theories correspond to explicit theories, they influence peoples' daily practice of creativity development. The influence tends to be more impactful in those who are still in the process of developing their creativity, such as in children. This is one of the reasons that educational settings have gained attention in implicit theory research. In contrast, less research has explored how creativity is perceived in other populations. For instance, how scientists perceive creativity is different from what engineers, or more dramatically, artists, perceive. Differences in implicit theories by profession may elicit characteristics unique to each domain, which might help to build a model explaining creativity specific to a domain. Implicit theories can be compared within a profession across a professional path; what engineering students perceive about creativity is likely different from what seasoned engineers perceive. Comparing the differences contributes to uncovering how domain-specific creativity is developed, how implicit theories affect its development, and what challenges people may encounter across a professional path.

Another challenge is that mixed evidence about creativity can be easily spread among the public. The media plays a big role in this dynamic. For instance, the "mad-genius" theory refers to the notion that creativity seems to be connected to negative aspects of mental illness. The mad-genius theory is often romanticized in the media and is prevalent in public discourse, as if the theory has been scientifically confirmed beyond dispute. Perhaps one of the reasons for this is that the romanticized notion may be profitable in the media although it is not empirically supported; Paek et al. (2016) synthesized 89 studies and found that common psychopathologies (e.g., anxiety, depression) were not really related to creativity in general and even negatively related to creativity when those psychopathologies were as serious as being diagnosed clinically. Despite the unsupported connection between them, the mad-genius belief affects how people perceive their own creativity. The stronger they believe in the mad-genius theory, the more likely they rate themselves more creative, whether or not they are actually creative. This finding indicates that a false belief discourages them to accurately estimate their creativity, which could impact how they allocate their efforts and resources to be creative. Therefore, scholarly endeavors are compelling in identifying prevalent misconceptions regarding creativity and informing the public.

It is the most normal thing in the world to improvise. We improvise every time we say a sentence, but we are told in our veneration of the masters that the creative process is some sort of mysterious and godlike thing only possessed by a few people – when in fact we are improvising all the time, creating all the time

Stephen Nachmanovitch (Quoted by Channing Gray, 1990).

When people encounter the word *improvisation* they readily think of music and, specifically, of Jazz music, where improvisation is a core element and highly valued. Yet, improvisation can be found in nearly any area of life and is a prevalent feature in many human activities; indeed, we all improvise on a daily basis, when we communicate with each other. This chapter is focused on creative improvisation and touches upon several aspects involved in improvisation as a unique form of creativity. It starts with defining and describing the concept of improvisation; then looks at improvisational creativity in different domains, starting with performing arts (music, theatre and dance), moving on to describe improvisation in martial arts and then to studies on the role and manifestation of improvisation within organizational and work context. The chapter finishes with a brief review of several studies pertaining to neural and cognitive aspects related to improvisation.

What Is Improvisation? Concept Definitions and Descriptions

On the one hand, as Nachmanovitch noted, improvisation is one of the most natural and prevalent human activities: most human interactions include improvisational elements. On the other hand, improvisation is a unique form of creativity, considered a desirable and, somewhat illusive skill, not only in a host of artistic domains ranging from music to theatre to dance but also in many various professional and organizational areas. This apparent contradiction is part of what makes improvisation an interesting and somewhat complex area of study.

To start, it would be instructive to examine the etymology of the word, going back to its Latin origins: *provisus* means foreseen or provided for (in advance), whereas 'im' indicates a negation or opposite of the word that follows. Hence, *improvisus* is something that is unforeseen, not prepared beforehand. According to Cambridge Dictionary (Improvisation, 2019), improvisation is "a performance that is not practiced and that is invented by the performers" and "the activity of making or doing something that you have not planned, using whatever you find." While the first definition is limited to performance, mainly in music, the second definition pertains to a broader set of activities. Yet, both definitions are not sufficiently exhaustive in describing the range of actions and phenomena where improvisation can take place.

Improvisation differs from many other types of creative performance in that, in improvisation, *the process is the product*. Unlike a scientific or artistic project in which the process of creating leads to some kind of end-product (tangible or not), in which the trials and errors along the way are usually 'edited out' and, generally, do not constitute an explicit part of the final outcome, for the improviser, the creative path is the end (Eisenberg & Thompson, 2003).

Gridley (1985) stated that "to improvise is to compose and perform simultaneously" (p. 4). Brownell (1994), who conducted research on drum-set improvisation in jazz, brought several other definitions: the first one by Horsley, who defined improvisation as "the creation of musical work, as it is being performed," and a somewhat different one by Tirro: "the somewhat mystical art of performing music as an immediate reproduction of simultaneous mental processes" (p. 28).

Sawyer (2000a) sees improvisation as an element of performance genres where there isn't prescriptive notation and he includes verbal-based as well as music-based genres in this area. He gives ritual, gossip, negotiations greetings and conversation as examples of verbal genres that fall under improvisation.

Sawyer holds a non-dichotomic view on improvisation; that is, rather than classifying creative endeavors into improvised and non-improvised, he sees improvisation as a relative quality or characteristic of performance. Writing about verbal improvisation, he believes that “improvisation is not an absolute, but rather a relative term, and is always in a dialectic with the pre-existing structures of verbal performance” (p. 121). To answer the question of what makes a performance more or less improvisational, Sawyer suggested a multi-criteria approach with seven dimensions along which performance genres can be contrasted, with each dimension indicating a more ritualized vs. improvisational character: *Ossification*, a term borrowed from anatomy, refers to how archaic versus contemporary is the language used; *Involvement of audience*, where more improvised genres tend to include more interaction with and participation of audience in the performance; *Resistance of genre to change*, with more improvisational genres being more open to change and innovation; *Permanence of genre change*, which indicates that while changes are more likely to occur in highly improvisational genres, these changes do not persist; *Cultural valuation*, with more ritualized genres gaining higher social and cultural value than improvised genres; *Indexicality and metapragmatics*: Sawyer said that in more improvised genres speakers make higher use of references to specific elements in the performance itself and reflecting on their own performance while performing it; *Breadth of genre definition* refers to more improvised genres having a broader or more tolerant approach to include variety of performance elements, where such diversity is more likely to be treated as error in more ritualized performance genres.

Sawyer’s typology is a useful and sophisticated approach to compare the degree of improvisation in certain performance genres. Questions remain as to how useful this approach would be outside linguistically based performance genres, such as music, organisational improvisation or improvisation in dance and movement. Also, a further discussion is needed as to which of these dimensions are more crucial and important in certain performance genres; it is likely that some of the dimensions would be more relevant for some performance domains than others. For example, in certain artistic and social sub-cultures, such as Hip hop and, specifically, in the freestyling kind of Rap music, improvisation is an essential element of the performance and, thus, the dimension of cultural valuation may not function in it at the same way as it would in classical music.

Improvisation in Music

Most people tend to associate the term improvisation with music-related performance. Musical performance necessitates a set of motor and cognitive skills that are somewhat different from those required for performing well in other artistic domains (Gabrielsson, 1999; Thompson, 2009). Within musical performance, improvisation represents a specific sort of performance, typified by a combination of both high technical skills as well as originality (Pressing, 1988; Sawyer, 1992).

There are several characteristics which distinguish improvisation from other forms of creative musical activity. Gridley (1985) characterized improvised music as spontaneous, unrehearsed, and not written-down. Musical improvisation differs from other musical performances in that it does not require the performer to remember or follow set music and, unlike in most other musical performance, the absence of musical score that serves as benchmark for evaluating the characteristics of performed music. More than in other musical performance genres, innovation and originality are central and explicit goal among improvisers who try to avoid drawing on musical patterns or repeating rehearsed music.

Acknowledging that all performances include at least some degree of improvisation because not all the parameters of music can be fully specified in a musical score, Thompson (2009) tried to answer the question as to what, specifically, distinguishes musical improvisation from other musical genres. To that end, he employs the distinction between primary and secondary parameters of music. Performers of typical music are mostly limited to alter secondary parameters of music, such as loudness, timing, timber and tempo. In contrast, improvisation musicians show their skill in working with altering primary parameters, such as pitch, harmony and rhythm. By expressively manipulating primary parameters, improvisers create music that is more unique and original than music performed by musicians who interpret existing musical text. At the same time, Thompson reminded us that even improvised music is not completely original since it has to be based on some knowledge of existing music. He pointed out that the question as to how improvisers convert their memories of past music into new and original music performance is still not sufficiently answered and is a potent area for future research.

Brownell (1994) added another point: improvisation is mainly a practice which is being learned through personal experimentation and by oral tradition as opposed to structured written manuals and organized pedagogical materials, which characterize more the learning process of more “structured” musical performance.

Becker (2000) discussed the issue of etiquette in improvisation, that incorporates the notion of respect, that musicians show towards each other as well as the audience. He described how that respect may be lost by fellow musicians when a member is taking too much time and space improvising or ignoring completely others’ input as well as when egalitarian principles, which Becker argues are dominant in Jazz music, are violated. Audiences can perceive lack of respect in improvisation when musicians seem to ignore the audience reactions and focus on playing with each other.

Although Jazz is, by far, the musical style most associated with musical improvisation, improvisation in music is not limited to Jazz. Among the musical styles that emerged in more modern times, Rap music includes multiple occasions where improvisation is enacted; specifically, *Freestyle* rap is an improvisation style that is performed with or without instrumental beats and where lyrics are recited without strict planning or fixed structure. Definitions of what freestyle rap is vary and are often informal, as befits a performance area that only fairly recently became a subject of academic studies. Hisama (2016) noted that the definition of freestyle changed from the 1980s when it initially was used to refer to rap that wasn’t focused on a specific topic, emphasizing the random aspects of verbalization. In more recent years, freestyle is more specifically referring to rap that has not been written or prepared in

advance, thus, emphasizing the spontaneous nature of the performance: “Freestyle is you being spontaneous [he snaps]: right now. Improvise: *right now*, On the spot” (Rifleman, in a documentary film by Fitzgerald, 2004, quoted by Hisama, 2016).

Most performances are solo and, typically, a strong emphasis is placed on rhyming verses. While the performance itself is typically solo, it is most often performed in a group context, akin to a jam session, called *Cipher*, where a group of people stand in a circle and take turns improvising rhymes, typically informally. A specific variation is a freestyle battle, where performers compete to establish who is best, with the audience determining the winner. Interestingly, in freestyle rap, not unlike in Jazz, the question has received attention as to what type of creativity underlies improvisation: a pure spontaneous act versus mostly spontaneous performance but one that is based on preparation. Some freestylers noted that their art is a craft that involves training and continual work to “transform words into coherent verbal expressions” (p. 251, Hisama).

While various aspects of music performance received considerable attention by psychologists, there have been only a few empirical studies of music improvisation in the social sciences and even fewer that looked at improvisation from a psychological perspective. One reason may be that it is more difficult to capture and study a dynamic process of creativity than it is to study a product of creative process.

In a study of improvisational creativity in jazz, Sawyer (1992, 1999) conducted a series of interviews with professional jazz musicians. While he focused on *small jazz groups*, his observations and discussion are relevant to other forms of musical improvisation as well. Sawyer identified three critical aspects of improvisation, as follows:

- 1) *Interactional influences*: in improvisational performance, the social group is present and contributing to the creative act, as it occurs. In jazz, the social-environmental context strongly influences the nature of the improvisation, including the musical structure.
- 2) *Conscious and nonconscious processes*: Many improvisational musicians express preference for a mental state during the performance in which the ‘intellectual’ side is minimized. In comparison to composition, improvisation, evidently, relies more on ‘intuitive creativity’ versus ‘analytic creativity’ (though jazz musicians definitely use the latter one as well).
- 3) *The balance of structure and innovation in the domain*: in music improvisation, innovation is the primary goal and ‘breaking the rules’ is recognized as essential to creative jazz performance. Nevertheless, the musicians are aware of rules for how to innovate, as well. The salience of the tension between ‘breaking the rules’ and, on the other hand, accepting the rules about *how to break the rules*, distinguishes jazz from other artistic and scientific fields.

Music improvisation is typically learned through personal experimentation and only rarely through written manuals and pedagogical materials, which are commonly found in learning processes of more ‘structured’ musical performances, such as classical music. While, until recently, it was rarely taught in a systematic way in music education programs (Thompson, 2009) increasingly, improvisation is treated as an important skill in music education. For example, McPherson (1993), after examining a test that measures improvisational skill, noted a positive correlation between improvisational ability and performance proficiency.

Following an extensive review of historical, ethnomusicological, and psychological evidence, Pressing (1987, 1988) proposed a cognitive model in which improvisation is construed as an ordered sequence of ‘event clusters’. Each event cluster may be associated with previous events but is also shaped by current goals. Two strategies of continuing an improvisation are used: *associative generation* and *interrupt generation*. In associative generation, the performer continues the improvisation by introducing materials that are either similar to or contrasting with previous event clusters. In interrupt generation, the performer introduces novel musical ideas that are unrelated (neither similar, nor contrasting) to previous events.

Improvisation in Theatre and Comedy

Improvisation in theatre appeared in ancient times, such as the Atellan Farce performances during the ancient Rome periods; however, as a distinct and developed genre, improvisational theater and comedy, often referred to as *Improv*, predominantly developed during the second half of the 20th century. In improv, most or all what is performed is unplanned or unscripted but, rather, created spontaneously by the actors/performers. Improvisational acting can be found in comic or non-comic variety, in stand-up comedy, in theatre plays, in psychodrama workshops, and in sections of filmed content (e.g., scenes in *Taxi Driver* and *Good Will Hunting*).

In theatre, Spolin (1999) was among the early pioneers of improvisational performance styles and also created techniques that can be used to develop improvisational skills among actors. A specific genre of theatrical improvisation is the political improvisation emerged in several countries, such as Poland (Jerzy Grotowski) and South America (Augusto Boal’s *Theatre of the Oppressed* Boal, 1993).

Building on Spolin’s work, improv comedy was later developed, initially in the US, then spreading to other countries and continents. Improv comedy sometimes takes suggestions or ideas from the audience to shape the performance. Improvisation is also often used by stand-up comedians who perform solo in clubs; while most of what stand-up comedians perform is pre-rehearsed and planned, some comedians integrate spontaneous elements, including interaction with the audience and as a way to deal with hecklers.

A core principle in improvisational comedy is known as “Yes, and ...”. Yes, and ... refers to the norm that a performer is expected to accept what another performer said or suggested and then build upon it in their own performance, resulting in a collaborative creative scene. The “Yes, and ...” principle distinguishes improv theatre from more traditional theater forms, where actors follow pre-determined scripts. While improv theatre is very flexibly in terms of structure and content, it is not without structural elements,

which can be classified into *external* and *internal*. External structure is shaped by suggestions from the audience and the type of venue and event that the improv takes place in. Internal structure, in contrast, is not obvious or evident to the external audience and is informed by 'rules' and principles known to the actors alone.

The 'Yes, and' principle is supported by several such 'rules', found in many theatre improv performances: refraining from judging one's own and other's ideas, active listening, and thinking without pre-determined criteria (that is, being open to various interpretations of an act or verbal information; [Moshavi, 2001](#)). Chicago's Second City, one of the most influential comedy theatres in the world, adopted and further developed these 'rules' into theatrical techniques.

Improvisation in Dance

Improvisation in dance can be found in various traditions, eras and cultures including Argentine Tango, Spanish Flamenco, Middle-Eastern Belly Dance, Indian tala, American Break Dance and Blues Dance and western-originated modern dance ([Carter, 2000](#)). However, the most radical form of improvisation can be found in a dance genre called Contact Improvisation (often referred to as *contact* or CI in the dancing circles).

Contact Improvisation typically involves a duet of dancers (though it can be performed as solo dance or in groups as large as ten or more dancers) who move together without agreed choreography or pre-planned script. They respond to each other's movements while spontaneously generating and creating their own way of moving with the partner, with themselves and in the specific space they are in. Contact dancing can be performed with or without music but, almost always, without speaking (which supports a better presence to one's own movement ideas and to the partner's movement). Dancing in Contact is a radical form of movement improvisation as there are no roles and no fixed rules and, ultimately, no expectations of what the next move would entail. The framework is very flexible and, while there are no fixed rules (nor agreed definitions) of what Contact is, most experienced CI dancers practice some of the following qualities: being active and reflexive, harmonic and spontaneous. Dance partners may engage in diverse forms of bodily contact through different parts of their body with an emphasis on high connection of body and mind and maintaining high levels of conscious touch. Dance actions may involve rolling on the floor or on objects (e.g., chairs), rolling on each other, pushing, sharing and taking each other's weight, jumping, falling.

The quality of a Contact dance is hard to evaluate by external standards though observers note differing outcomes of originality, harmony and flow among the dancers. While certain basic physical ability is helpful in mastering CI, prior formal dancing practice can be both an advantage as well as disadvantage since dancers often bring the set roles and movement they learned into CI, thereby curtailing their availability to improvise and flow with whichever move that comes from their partner. As a movement partnership that can get very physical, advance CI practice necessitates high levels of trust and awareness, supported by interpreting and acting on continuous multi-sensory feedback. Since its initial development as an experimental modern dance in 1970s, CI has spread from the US to many other countries and practiced in different levels of intensity, often taking the form of a *jam*, which is an informal contact dance gathering ([Carter, 2000](#)).

Improvisation in Martial Arts

While most martial arts combine well-rehearsed elements with improvised movement and response, the opportunity and, indeed, the necessity, to engage in improvisation is at its most in sparring practice or competitions. Most martial arts forms practiced today were developed in East Asia, with the majority coming from either Japan (e.g., Judo, Karate, Aikido) or in China (e.g., Kong Fu, Wushu). Training in most martial arts is based on mastering well defined moves and motions, often in sets of moves and rehearsal of attack-response sets. Not unlike in dance and music, improvisation in martial arts necessitates not only a certain state of mind but a high level of skill and practice. Effective martial arts improvisation can only be practiced once after extensive training and certain level of mastery.

A good example of martial art system where improvisation is built-in systematically into training is Bujinkan, an international martial arts organization, which was founded by Masaaki Hatsumi, who serves as its current head. Bujinkan is based in Japan and comprises several schools that are based on modern adaptations of samurai martial art tactics, where students learn to master techniques based on several underlying principles that include timing, distance, angle, strikes, locks and throws. Thus, students first master predefined sets of movements known as *Kata* and undergo physical conditioning. Once they progress and are skilled enough, they are encouraged to engage in what is called *Henka* in Japanese. *Henka* refers to a quality that is improvisation like, where practitioners engage in variations on the fixed routines in order to respond effectively to changes in the attacker's movement and situation. Putting the kata and henka training into practice is done through Randori, a free form training aimed at simulating realistic combat situations. Randori training involves spontaneous responses and dynamic techniques where the defender uses various means to disarm or control the attacker ([Hatsumi and Cole, 2001](#)). According to an advanced student of Bujinkan: "The experience of training with Hatsumi Sensei in Japan is that he never really does the same thing twice. He tends to explore a principle and formulate many variations around a central core." ([Fakhfakh, 2019](#)).

In the modern and eclectic martial art Cheng Hsin, which was created by Peter Ralston by incorporating Zen principles and techniques from Tai Chi, Aikido, Pa Kua, Judo and Western Boxing. In Cheng Hsin, improvisation is encouraged from early training stages. Students are encouraged to explore freeform movement applying the principles of keeping a calm mind, relaxed body, grounding, and moving the whole body as one. Reminiscent of contact improvisation, Ralston

developed a set of game-like practices to train students in developing flexibility when interacting with another person. Through gradual increases in intensity and speed, these freeform games turn into sparring (Fakhfakh, 2019; Ralston, 1999).

Improvisation at Work and in Organizational Context

Until relatively recently, improvisation, was mostly studied in the context of some sort of artistic performance; however, in the last couple of decades, improvisation has been increasingly appearing in work and organization studies. One of the reasons that improvisation has only relatively recently become a focus of study and research in organizational studies is that, traditionally, the emphasis in most organizational theories has been on elements of order and control; even the term itself, 'organization', brings to mind concepts of order and conscious organizing. This emphasis on ordered and planned dynamics and actions left out of the discussion many work related aspects that don't fit into this well-organized theoretical framework (Weick, 1998). I suggest that the increased popularity of discussing organizations in terms of improvisation and employing metaphors that are based on the worlds of music and theatre improvisation is due to the increased emphasis, both in organisational academic studies as well as in practice, on creativity and innovation, flexibility and timely and agile response to rapidly changing economic, organizational and social environments.

Weick (1998) suggested theoretical tools to understand improvisation and used concepts from Jazz improvisation to shed light on organizational improvisation dynamics. He discussed how improvisation as a practice ranges in degrees, with increased demands on imagination and concentration. These gradations, that exist in musical performance, can be applied to organizations in describing dynamics that take place during the development of new products, a process rife with change and innovation. Because improvisation dynamics lead to faster ability to tackle changes and result in creativity and innovation, an organization that learns how to improvise, holds a sustainable competitive advantage.

Moorman and Miner (1998) laid foundations for the concept of *organizational improvisation*, which they defined as "the degree to which the composition and execution of an action converge in time" (p. 698). They suggested that organizational skill knowledge (procedural memory) and knowledge of facts (declarative memory) moderate the impact that improvisation has on organizational outcomes. They stated that improvisation influences organizational memory by (A) generating experiments and (B) creating a context where improvisation competency skills can be developed. The authors observed that technological change influences the value of organizational improvisation and, furthermore, organizations' ability to substantially alter organizational memory's content and access effectiveness. They concluded that procedural memory enhances improvisational effectiveness and speed, while reducing its novelty. Declarative knowledge, on the other hand, enhances improvisational effectiveness and novelty, while reducing its speed. Thus, to achieve optimal benefits of improvisation, an organization should develop competencies in both types of memory.

Some organizational scholars attempted to move beyond the often-used Jazz-based metaphors when discussing organizational improvisation. Kamoche et al. (2003) warned against the reliance a single phenomenon when developing a new theoretical area; they suggested that organizational improvisation theories should look to Indian music improvisation, in addition to the traditional Jazz-as-metaphor, to create a more complete and accurate models. The Indian music model would be especially relevant for managers who aim to create specific parameters within which improvisation by followers would occur or when a competitive atmosphere is sought. On the other hand, they recommended that managers use the music therapy model when managers wish to create an innovation culture in a dysfunctional organizational culture where initiative-taking and decision-making are hampered and where skill levels are relatively low.

Fisher and Barrett (2019) emphasize the importance for organization scholars to focus on the experience of improvising because improvisation is an important source of creativity, which became a crucial element of many organizations' performance and, even, survival. They contrast improvisational process with compositional process, pointing out that while composition has been modeled as moving through certain phases, mostly in a linear fashion, improvisational processes are at odds with such phase models because the purposes of actions aren't well-defined in advance but, rather, next steps emerge as actions unfold and goals become clear only in retrospect. They observe that, like in music and theatre, improvising at work is risky because "improvisers test the limits of their own capabilities and sometimes fail in embarrassing ways." (p. 151). They suggest that it is the danger of failure that makes improvisation simultaneously exhilarating and perilous. While improvisation brings with it excitement in various work roles, they warn that constantly improvising on the job can lead to burnout and, sometimes, to successful improvisers resigning as the demand to constantly improvise becomes more tedious than exhilarating. They conclude that "The experience of ideating and enacting without the possibility of revision is central to understanding what improvisation is. That experience is both fearful and exhilarating, holding within it the possibility of both transcendence and failure." (p. 159).

A recent study by Secchi et al. (2019) was the first to describe and assess Service Improvisation Competence, a new construct that constitutes a novel way to improve customer experience in high-contact service contexts. Serv-IC is "the systemic ability of a service firm's employees to deviate from established service delivery processes and routines to respond in a timely manner to unforeseen events using available resources." (p. 1329). Studying the hotel industry authors found that while service improvisation competence had a strong positive impact on customer satisfaction in lower-level hotels (1–3 stars) it had only a weak relationship to customer satisfaction in elite hotels (4–5 stars).

Neuro-Cognitive Aspects of Improvisation

Substances Affecting Improvisation

Consumption of Cannabis products is part of several musical sub-cultures and many musicians reported that their musical performance is enhanced through cannabis use (typically in the form of marijuana smoking). Some jazz musicians reported that marijuana facilitates improvisation. Thompson (2009) suggested that this effect may relate to the effect of marijuana on time perception, which often seems to slow down. This effect has been validated in the lab, where participants tend to overestimate the amount of time passed in time perception tasks. Some jazz improvisers claim that this altered time perception gives them greater insight into “the space between the notes.” The subjective experience of this altered time is that musicians perceive that they have more time to make spontaneous musical decisions. “There may be a partial neuropsychological explanation for this subjective experience. A marijuana high is experienced when the psychotropic compounds in cannabis (primarily THC) are metabolized by cannabinoid receptors in the brain. The cerebellum—long known to be implicated in time perception, particularly for the smaller time intervals important to music—is known as an area of the brain with high concentrations of cannabinoid receptors.” (Thompson, 2009, p. 176).

Cognitive and Somatic Aspects

Attention to the here and now and acute awareness to the presence of one’s improvisation partners appears as a cross-cutting theme in music, dance and martial arts. Effective collective improvisation requires that each member of the improvising collective (e.g., dance group, Jazz band) pays attention, in real time, to what others in that group are doing, while performing their own part. Becker (2000) refers to it as *Etiquette of Improvisation*, which is typified by “attentiveness, care and willingness to give ground and take direction from each other involved in that kind of improvisation”.

Related to the above, physical embodiment is central to several improvisation domains, especially in performing arts. Bourdieu uses the term *Habitus* in his discussion of persons’ participation in various activities, termed broadly (and metaphorically) as games. *Habitus* “means basically the embodied sensibility that makes possible structured improvisation” (Calhoun, 2003, p. 292). According to Bourdieu, Jazz musicians and other skilled improvisers can play well together without consciously following rules because they have developed the ability and skill to use their bodies and senses to effectively interact with other musicians in real time. As discussed in the present chapter, this ability to ‘let go of rules’ while ‘playing with others’ can be found in several areas such as martial arts and contact improvisation. The common theme is that to reach a state of seemingly effortless flow, performers need to rely both on developing technical skills as well as learning to be constantly aware of their senses and somatic information from their own body as well as others.

Spontaneity

Spontaneity is another element that appears in various discussions of improvisation; referring to the unplanned production or performance of art, music, movement or speech (Becker, 2000). Does the emphasis on spontaneity mean that there is no structure, or no planning involved in improvisation? Thompson characterized spontaneous creation of musical compositions as one of the core elements of improvisation in music saying that “some improvisers may try to minimize all musical planning prior to their improvisation and focus on spontaneous innovation.” (2009, p. 199). Sawyer (2000b) acknowledged that the concept of improvisation is “problematic” because structure is present in improvisation as well, but it is not clear how little structure would need to be present in order for something to qualify as improvisation. Sawyer’s conclusion, drawing predominantly on his performative and academic experience with music, is that “there is no sharp dividing line between “improvisation” and “not improvisation” but it is rather a continuum (p. 182, 2000b). The degree to which improvisation relies on structure vs. spontaneous creation is a ripe area for both theoretical as well as empirical future investigations.

Introduction

Creativity is recognized as an essential skill for individuals and a necessity for both survival, development, and growth of organizations, but the question *what is creativity* is often answered in too many different ways or in very broad terms. For example, when we talk about famous creatives, like Einstein, or some radically new inventions like the iPhone or the light-bulb, creativity is often construed as a highly desirable, but often elusive phenomenon, with extremely high expectations and standards, and some mysteriousness surrounding the concept and the process leading to the creative outcome. At the same time, everyday creative ideas of ordinary people, which often provide a quick fix to a problem or just adapt a solution to make it more efficient, like using different colors to make objects more noticeable and increase safety, or creating a new sorting system, are equally valuable and necessary and may be considered equally novel and creative. In recent years, an explosion of research in different areas has explored a plethora of personality and contextual factors and the interactions among them that may facilitate or constrain creativity, but the results are mixed and inconsistent, and some of the conflicting findings may originate from this very broad definition, the homogeneous and uniform way we usually measure creativity and the fact that some studies do not capture the full spectrum of creative ideas but only radical (for example new inventions and patents) or only incremental (e.g. Ideas from a company suggestion system). In this respect, some differentiation of the different types of creativity may help us both explain the factors and processes that influence it, as well as stimulate more creative idea generation.

While creativity is often defined as the production of ideas about products, processes, or procedures that are novel or original and potentially useful or practical (e.g., Amabile, 1996), creative ideas can range from minor adaptations or changes in how work is performed to radical breakthroughs and completely new products (Madjar et al., 2011; Mumford and Gustafson, 1988). One emerging area of research considers creativity as not just one overarching construct (Madjar et al., 2011; Unsworth, 2001), but rather as comprised of two or more different types. These two types include a more incremental, adaptive creativity whereby small changes are made to existing products, processes, or solutions to create a novel and useful idea; and more radical creativity, in which new and revolutionary ideas are introduced to completely transform existing products or processes. Several influential studies have differentiated creative work that relies on familiar algorithms and minor adaptations from the creativity that depends on radical new discoveries. Other studies have differentiated the factors for radical and incremental innovations and between exploitation and exploration, adaptive and innovative thinking, so the idea that there are different types of creativity is not new. Creativity entails an idea that is both novel/original and potentially useful/practical, two very different criteria for idea evaluation. Depending on the prevailing or salient aspect of the creativity definition, an idea could be really novel and original or not so new but very practical and useful, thus to understand creativity better, it may be useful to classify it into different types, namely, radical and incremental. Madjar et al. (2011) have defined radical creativity as ideas that substantially differ from the existing practices of an organization. Highly radical ideas present new and set-breaking frameworks or processes. By contrast, incremental creativity implies few changes in the frameworks and offers only minor modifications to the existing practices and products but usually with substantial usefulness. Making this distinction between radical and incremental creativity may allow us to better recognize the importance and value of both and tailor the contextual factors to stimulate more one versus the other. In certain situation, an incrementally creative idea may provide a quick and very economical fix to a problem or at least assure efficiency in the solution - in others, incremental changes may not be enough and a radical breakthrough may be what we need. It is important for both creativity research and practice to make this distinction between incremental and radical creativity instead of grouping everything together as a way to untangle the complexity of the creativity phenomenon and to create a better and more useful framework that will allow us to understand the different factors influencing creativity.

Relation Between Radical and Incremental Creativity

While it is easy to define the two types based on the degree of novelty and usefulness that they entail, incremental and radical creativities are neither completely segregated concepts nor concepts that can compare in terms of superiority. While individuals exposed to the full range of creativity, for example in advertising agencies, may easily classify an idea as incremental or radical, people who do not have enough experience with creativity or who have not been acquainted with both radically new and incremental ideas may have a hard time differentiating them. It is important to point out that radical creativity, although often easier to recognize, is not necessarily more valuable than incremental - on the contrary, because of the reduced risks involved, organizations may sometimes seek and value incremental ideas more as they can easily see the value added they bring. Unlike incremental ideas, radically creative ideas are usually easily recognized as novel and sometimes, we see the initial idea as radically new but a lot more creativity (often of the incremental type) may actually be involved in the small modifications and improvements of this initial idea till a final complete outcome is reached. For example, as Malcolm Gladwell states "The modern disposable diaper was invented twice, first by Victor Mills and then by Carlyle Harmon and Billy Gene Harper" (Gladwell, 2001). While Mills is recognized as the "father of the disposable diaper" and he was the one who created the initial product, and later the market for disposable diapers in 1961, it was the absorbent polymers created by Harmon and Harper, which led to thousands and thousands of incremental changes of the materials used, absorbent capacity, shape, bulkiness of the diaper, which later affected their transportation, distribution, storage, price, quality and convenience. But while Mills is celebrated for the creation of the disposable diaper, the incremental changes due to the small size of the new absorbent polymer created by Harmon and Harper are usually not recognized as a big accomplishment, while they are the ones, which added the most value (Gladwell, 2001).

In addition, in certain situations, a radically innovative outcome could be achieved by a series of incremental modifications and changes. For example, the new Nest thermostat, as a product, is nothing new and is still fundamentally having exactly the same function as the traditional old-fashion thermostat, but by incorporating the use of smart technologies, additional sensors and intelligent algorithms, it understands consumer preferences and can communicate to other devices. Through these small modifications, the company has created a new market for thermostats and a radically different "connected user" experience. Google's Gmail is another example of incremental creativity and innovation. When it was initially launched, Gmail had limited features but delivered emails well. Over time Google released more features and made the service better, faster, and easier to use and improvements continue to happen, so comparing the original and the current gmail, one may characterize them as radically different, although this was achieved through very gradual and incremental changes. As these examples illustrate, incremental ideas are not about huge sweeping changes, they usually improve an existing process or product, making it more efficient or cost effective. Radical ideas on the other hand, although rare, may suggest a completely new product, or a completely new delivery system (Blockbuster vs. Netflix) and may be disruptive to a company or a whole industry.

An idea or other creative outcome could be characterized as either incremental or radical, and the two concepts are seen as orthogonal and associated with differential pathways (e.g., processes and boundaries). The interpretation of the situation and its requirements and the approach and motivation that prompt incremental creativity are expected to be different from the factors that directly induce radical creativity (Amabile, 1996). At the same time, a series of incremental ideas and changes (e.g., changing colors [from pastel to bright], sound, and music; changing the individuals targeted [college students vs. retired baby boomers]) could eventually lead to a radically different advertising scheme. Ford (1996) has suggested that creative and habitual actions are competing behavioral options and incremental and radical are two types of creativity that pertain to behavior outputs that are manifested differently as individuals cope with a problem or situation. Kirton (1976, 1994) proposed that the difference between incremental and radical creativities probably stems from the different creative styles of individuals. Employees with adaptive styles work within the existing structures to make incremental changes and — do things better. By contrast, employees with innovative styles treat the current structures as part of the problem and create more radical changes by — doing things differently (Kirton, 1976). To further our understating of the creativity construct, it is important to not only classify ideas as incremental and radical but at the same time understand the antecedents and processes promoting one type of creativity more than the other and what follows is a brief summary of what we know about the differences.

Antecedents and Processes Leading to Radical and Incremental Creativity

One of the reasons for differentiating radical and incremental creativity are the important differences in how certain conditions may influence different creative processes. Oldham and Cummings (1996) for example, find differential results for two types of creativity measures (ideas from an employee suggestion system and patent disclosures) and argue that one explanation for these differences may be that their two measures captured different types of creativity, and the radical versus incremental distinction that appears in the innovation literature may hold with respect to individual-level creativity as well. A better understanding of the factors and processes contributing to radical versus incremental ideas may enable organizations to conditionally encourage or discourage radical or incremental creativity in their employees, align their work factors in order to achieve their desired goal (i.e., radical or incremental creativity). For example, within an organization, managers in an R&D department might want to have processes in place that foster and encourage radical creativity. In contrast, the managers of an accounting department may prefer to encourage incremental creativity and help their employees seek ways to improve on what is currently being done. Establishing the desired

conditions for appropriate idea radicalness should more effectively motivate employee idea production that is both supported, recognized and appreciated by managers and leaders and useful to an organization.

It is important to understand the motivational mechanisms as well as the personal and contextual factors that influence the engagement and the different cognitive processes involved in generating incremental vs. radical ideas. More specifically, identifying the factors that represent social and contextual influences, or personality characteristics, that may prompt the schema or frame of reference for interpretation of a situation may be critical. These factors may influence both the individual's interpretation of the situation or issue at hand and, consequently, involvement in radical creativity vs incremental creativity, as well as the processes used to generate these ideas. In addition to the motivating factors, the established models of personal and contextual influences on creativity (Amabile et al., 1996; Woodman et al., 1993) suggest other conditions that may influence the development and sharing of more radical creative ideas but have little or no effect on incremental creativity and vice versa (George, 2007). For example, factors that promote change or are more individualistic in nature, like resources for creativity, willingness to take risks, and career commitment, have a stronger association with radical creativity than with incremental creativity. At the same time, factors like organizational identification, presence of creative coworkers, and conformity, which have an element of loyalty, followership, and compliance (e.g., Miron et al., 2004; Zhou, 2003), are ones that may encourage incremental modifications rather than radical changes.

Intrinsic Versus Extrinsic Motivation and Incremental and Radical Creativity

One of the most important determinants of the radical vs. incremental creativity divide may be the reason or motivation for engaging in creativity. A lot of the creativity literature has explored intrinsic motivation, or the excitement for idea generation, the wish to engage in creativity for its own sake, or the desire to solve problems creatively as an internal drive for creativity (Unsworth, 2001). In contrast, a requirement from the job or problem at hand, the available bonuses and rewards, or the pressure for a solution to an existing problem, may provide an external drive and "force" an individual to engage in creativity. Although both the external and the internal motivators should result in creativity, some research suggests that the type of creative ideas generated may be very different, and this may be why there are mixed results regarding the effect of intrinsic and extrinsic motivation on creativity. A possible reason for the previous conflicting findings may lie in the unitary measurement approach to creativity, with differences in radical versus incremental creativity obscured. For radical creativity, deeper processing, experimentation, and more mental persistence should be a key driver, whereas for incremental creativity, the reward or external driver may be a key motivating force. These differences in underlying motivation are important because as others have suggested (Amabile, 1996; Unsworth, 2001), intrinsic motivation will be more likely to facilitate the kind of cognitive processes necessary to yield radical creativity. On the other hand, external sources of motivation (e.g., external rewards and supervisor behavior or the pressure of the competition or the problematic situation) may have the potential to undermine intrinsic motivation (Amabile, 1996). In contrast, incremental creativity should be less dependent on deep cognitive processes and, in fact, may benefit from motivational factors that discourage deep thinking. Therefore, external motivators that draw attention to the continual search for adaptations, refinements, and improvement are likely to be more effective for incremental creativity. Reward or other external motivators signal that the change is desired and should encourage employees to seek creative alternatives, even if they are not inclined to do it on their own, thus extrinsic motivators may be a good way to stimulate incremental creativity.

Resources for Creativity

Resources for creativity are considered very broadly here and may encompass financial, material and expertise resources or the mere time, access to diverse information and leadership support, as well as self-esteem, and skills to think strategically and creatively. Previous studies have identified the availability of resources in organizations as a determinant of the level of creativity and innovation (Amabile, 1996; Damanpour, 1991). In other words, resources are needed to support both idea generation and idea sharing and implementation. Constrained resources will diminish both the ability and the motivation to come up with new ideas as individuals will not have the time nor freedom to be creative or will not see potential for the implementation of their ideas. Lack of resources for creativity is often a signal from the organization that radically new ideas are not valued there but the empirical results linking resources and creativity are rather mixed. From one side, both the generation and sharing of radical ideas require more resources (more diverse expertise, more time, more financial means to experiment) and involve more risks when shared, thus the availability of additional resources is needed to buffer these risks and stimulate radical idea generation. On the other side, most incremental ideas require fewer resources and effort to be implemented than disruptive or radical ideas, thus may benefit little from slack resources. Limited resources, while a constraint for radical ideas, may actually create the necessity for small adaptations and modifications in order to produce quick and efficient results without the need for additional means. Lack of resources may be seen as the reason for discovering new opportunities and a way to motivate creative problem-solution involving incremental ideas. Thus, the availability of resources for creativity in an organization, including non-financial resources as access to informational and emotional support and diverse information, may be a critical determinant for radical vs. incremental ideas.

Association With Different Groups and Social Context for Incremental and Radical Creativity

Even if the motivation is right and the resources for creativity are available, these may be necessary but not sufficient conditions for engaging in radical idea generation. Creativity, and especially radical creativity, is considered risky and to take the additional risk, individuals need to feel that they belong to a group that accepts their radical ideas, provides the necessary emotional and informational support for them, and serves as role models for the desired creativity. Individuals who provide a sense of belonging and acceptance are necessary to encourage the engagement in creativity and in this respect, the social context and the sense of belonging, identification and commitment to different groups may be critical.

Identification and commitment are related to the incorporation of a group's beliefs and values into one's own identity and self-image and the binding of the individual to an organization or social group. Individuals usually identify and experience commitment to multiple social groups – their team, department, organization, professional group, as well as friend and family groups. Stronger identity and commitment to any of the work groups entails job engagement and desire to perform well, as well as loyalty to the status quo and some compliance to established practices. But the foci of this attachment to a social group (i.e., team or organization as a local entity or career/occupation with a more cosmopolitan orientation) and which one of them is more salient may determine the interpretation of the situation and its demands and, consequently, be the driver of behaviors or tailor individual efforts towards more adaptations and incremental creativity or radical ideas for big changes.

A salient group identification usually signifies easy and natural access and communication to that group's members as a source of information and knowledge as well as guidance and acceptance. If the group is local, it may serve as a strong source of information from within organizational boundaries. Within their unit or team or organization, individuals may find additional expertise and repositories of knowledge, skills, and abilities that can be used in creating solutions to similar problems, they can also borrow methods and processes they observe from their colleagues, especially if they strongly identify with them and this internal scanning for information may be very helpful for incremental idea generation (Jaussi and Randel, 2014). Organizational or team identification (a more local orientation), may at the same time be the driver of social pressure for loyalty and conformity to established values and routines, which, although beneficial for routine performance and incremental ideas, may also trigger more compliance and inhibit the desire to be involved in radical creativity. It is important to note that although organizational identification, especially with a creative company, may allow engagement in creative behaviors, it is still associated with certain organizational constraints (e.g., ideas are evaluated by established processes, need to be accepted, and must match a certain image or established reputation) that may inhibit radical creativity and lead to more incremental ideas.

Commitment to one's occupation/career represents attachment to a more cosmopolitan group. Career/professional commitment may provide a broader, more open perspective that may, in turn, cause individuals to interpret situations as opportunities for growth and creativity and may provide more options for action and a diversity of acceptable alternatives. These interpretations and created meanings may motivate a higher level of engagement in creative action and behaviors leading to change and may provide the necessary support and initiative that will enable radical change and innovativeness. A cosmopolitan orientation will facilitate external scanning for information about industry trends, economic and marketing perspective or other insights from competing companies (Jaussi and Randel, 2014). It may provide access to more nonredundant information that increases the pool of knowledge from which to generate creative solutions (Perry-Smith and Shalley, 2003). While information obtained from outside the organization may not seem all that relevant to a problem or issue at first, a high commitment to the professional group providing the information makes it salient and helps with the connections, thus holds the potential to spark ideas that extend beyond modifications of existing practices and are more radical.

High career commitment may also mean less social pressure to conform, whereas high attachment to an organizational or in-group unit, more proximal in location, represents more requirements and demands than open opportunities. Thus, a salient commitment and identification with a career/profession, or a more cosmopolitan group orientation and belonging is expected to have a stronger facilitating effect on radical creativity than on incremental ideas. These associations with external to the organization individuals may provide both the necessary sources of diverse information, as well as the support and easier acceptance of new ideas and solutions, which enable radical idea generation.

Conclusions

In sum, to advance both research and practice in managing creativity, it is important to differentiate its different dimensions, specifically, radical creativity where the novelty of ideas is prevalent and incremental creativity, where their potential usefulness is the defining factor. Furthermore, the antecedents to both types of creativity seem different and a distinct combination of individual and contextual variables such as extrinsic or intrinsic motivation, resources for creativity, organizational or career commitment among others can differentially influence the type of creativity exhibited (Gilson and Madjar, 2011; Madjar et al., 2011).

As some studies do not capture the full spectrum of creative ideas and focus only on radical or only incremental creativity, it is important to understand the whole complex picture in order to use this knowledge to foster the right creative ideas. The fact that the two types of creativity appear to be motivated by different drivers suggests that it is very important for organizations to figure out what type of performance they seek before they attempt to boost creativity using or modifying one of these factors. Understanding how certain factors play a role allows managers to tailor their policies and employees to engage in processes related to the desired by the organization type of creativity.

While the definitions of radical and incremental creativity seem clear, individuals with little experience and exposure to creativity may not be able to easily classify every idea coming their way. Runco (2014) outlined several problems with dichotomous representations of creativity, while others have expanded the classification to four instead of two types (Kaufman and Beghetto, 2009) but this classification is useful as a way to broaden the conceptualization of creativity and highlight the value of creative ideas with different magnitude.

Historic Accounts of Incubation

Almost 100 years ago, the concept of incubation was popularized by [Graham Wallas \(1926\)](#), who made a landmark contribution with his book ‘The Art of Thought’, which helped to increase the understanding of the creative process. He coined terms that are still widely used today for four stages in the process: preparation, incubation, illumination, and verification. He conceptualized incubation as a stage in the creative process that follows hard conscious preparatory work involving acquiring knowledge and initial, unsuccessful attempts to come to a solution, and that ends at an impasse. At that time, the problem is set aside, and, in the following *incubation* period, the creator is no longer consciously working on the problem. The reason why the apparently uneventful incubation period of seeming cognitive inactivity has received so much attention in the creativity literature is, perhaps, best explained by what happens next: When the incubation period subsequently ends, it sometimes occurs in a sudden, satisfying, and surprising illumination or flash of insight that somehow resolves the issue at hand. Although illuminations may happen quickly, Wallas, in his original account, was quite fascinated with how one might sense—and become better at sensing—that an illumination might be near, a state he labelled “intimation”. The verification stage, which occurs when the creator is consciously thinking about the problem once more, ultimately involves evaluative processes and further work on the illuminated idea [cross reference Evaluative Processes].

[Wallas \(1926\)](#) derived his four stages of the creative process from anecdotal retrospective accounts by highly creative scientists, artists, and inventors producing creative contributions in their field. Indeed, anecdotal accounts of grand creators making breakthrough inventions, science, and art after spending time away from the problem are frequently quoted in the creativity literature (see The Four P’s of Creativity).

One of the most frequently cited anecdotal accounts of incubation comes from Henri Poincaré:

Just at this time, I left Caen, where I was living, to go on a geologic excursion under the auspices of the School of Mines. The incidents of the travel made me forget my mathematical work. Having reached Coutances, we entered an omnibus to go some place or other. At the moment when I put my foot on the step, the idea came to me, without anything in my former thoughts seeming to have paved the way for it, that the transformations I had used to define the Fuchsian functions were identical with those of non-Euclidian geometry. I did not verify the idea; I should not have had the time, as, upon taking my seat in the omnibus, I went on with a conversation already commenced, but I felt a perfect certainty. On my return to Caen, for conscience’ sake, I verified the result at my leisure.

Poincaré quoted in [Hadamard \(1945, p. 13\)](#)

This recollection by Poincaré has often been used to highlight that sometimes the creator is unable to identify “anything in their former thoughts” that generated the sudden shift from incubation to insight. However, other anecdotes in the literature can be used to show that is at least not always the case. Another frequently quoted anecdote involves Archimedes’ discovery of displacement after a long period of unsuccessfully trying to figure out how to estimate whether a crown was made of solid gold or not. The irregularity of the crown made it very difficult to estimate the crown’s volume, which would allow him to compare weight to volume. The story goes that, upon sinking into the water at the baths, Archimedes realized that he, by an external analogous event, had solved the problem—he could calculate the crown’s volume by putting it into a liquid and

then noting the level of displacement. The story goes that he subsequently jumped out of the tub and ran naked through the streets of Syracuse, shouting “Eureka” (I’ve found it).

The apparent triggering event does not always have to be external, as illustrated by another frequently cited anecdote involves Kekulé’s discovery of the molecular structure of Benzen while dozing in front of his fireplace. The nap came after difficult and cognitively demanding attempts to solve the problem, and, while dozing, he would find himself imagining the atoms still leaping about before his eyes. The story goes that he, in this dreamlike inner state, would imagine the atoms performing snake-like movements, upon which one of the snakes would begin biting its own tail. At that moment, Kekulé awoke in a flash, realizing that the molecular structure was a circular one!

A more recent anecdote involves the development of the Post It™ note at 3M by Arthur Fry. He was attending his church choir and became annoyed that his bookmarks kept falling out of his hymnal. In a sudden realization, he connected the issue with a new type of not-so-sticky adhesive developed by another 3M employee Spencer Silver that until then had not found its commercial use. The Post It™ was born. Although the creativity literature has focused on a limited number of these anecdotal accounts that seem to be endlessly repeated, a very large number of further incubation-like anecdotes can be found in the extant literature. Such anecdotes, however, tell little about the mechanisms behind the incubation phenomenon. As Boden (1990, p. 15) noted, what these anecdotes have described of the mechanisms behind incubation and insight can best be summed up as “the bath, the bed, the bus” (that is, they were sitting in the bath, lying in bed, or riding on a bus when all of a sudden ...). As such, the existence of anecdotal accounts should not lead to acceptance of the existence of the incubation phenomenon. After-the-fact introspective reports of mental processes are notoriously unreliable. In the case of Poincare, he based his own analysis of his creative process on the self-reporting of episodes that took place almost 30 years earlier.

Research by Howard Gruber on tracing idea development over time (e.g., through notebook studies of how Darwin developed the theory of evolution) has illustrated that often the creative process is a protracted construction taking place over years involving a multitude of small insights, rather than one overarching flash.

The anecdotal stories serve to illustrate the incubation phenomenon, but they do not prove the existence of such a phenomenon, nor do they prove that particular theories of incubation are true or false.

Theories of Incubation

A number of potential theoretical explanations for the incubation phenomenon have been proposed. These theories differ in several ways.

One notable difference between theories of incubation is whether the incubation period itself somehow provides *beneficial* steps towards a solution (e.g., by receiving cues from the environment or unconscious progress) or whether it simply helps recover a *temporary inability to make progress* (e.g., helping to overcome a temporary fixating state or inability to remember). Another notable distinction is whether the mechanisms involved in incubation are solely confined to the *autonomous* cognitive system (for example, conscious or unconscious work, overcoming fatigue) or to some *interaction* between cognition and environment (for example, encountering facilitating cues or the inability to make progress due to contextual fixating elements). It is important to note that the theories of incubation listed below need not be mutually exclusive and competing, as it is possible that there are many different ways in which the past inability to resolve problems may be overcome—thus, creating an incubation effect.

Below are some of the most well-known theories of incubation:

Unconscious Work

In his original account, Wallas suggested that active unconscious processing of the problem took place during the incubation stage. The term “incubation” is a biological metaphor suggesting that these unconscious processes “gradually mature” the solution. Much like the slow incubation of an egg ends with hatching a bird, the incubation of ideas ends in the “hatching” of the solution, in a sudden and surprising insight.

As noted by Wallas (1926, p. 86), “The Incubation stage covers two different things, of which the first is the negative fact that during Incubation we do not voluntarily or consciously think on a particular problem, and the second is the positive fact that a series of unconscious and involuntary (or foreconscious and forevoluntary) mental events may take place during the period.”

Variations of this theory of unconscious work have been proposed several times in the literature. Whether the mechanism is referred to as the unconscious, pre-conscious, or non- or off-conscious, it involves a solution being gradually developed that, in a next step, reaches conscious awareness. While theories of unconscious work are consistent with many anecdotal accounts, the theories rarely detail the mechanisms behind this unconscious processing, making them hard—maybe even impossible—to test experimentally. The lack of experimental testability led to suggestions that the theory of unconscious work should be put on hold until other more testable theories have been examined. Nevertheless, a theory on unconscious thought by Dijksterhuis and Meurs (2006) has suggested that, while conscious thought may be focused and convergent, unconscious thought is more associative and divergent. Furthermore, it has been suggested that mind-wandering may help explain incubation effects. Mind-wandering is a state of mind which occurs spontaneously and automatically when not engaged in cognitively demanding tasks and which seems to increase associative processing.

Facilitating Cues

The idea that facilitating cues or information from the environment is the cause of incubation effects has been proposed a number of times in the literature. It is usually accompanied by a theory that the mind is cognitively prepared to notice these cues—thus, epitomizing Louis Pasteur’s notion that “chance favors the prepared mind”. [Olton \(1979\)](#) argued that a basic way to demonstrate the facilitating nature of cues could simply consist of telling a problem solver the answer to the problem during incubation! However, he argued, more interesting and realistic results could be obtained by varying how “obvious” the cues given are in a series of research studies.

As it happens, this is exactly the path that the analogical problem solving literature has taken. It began with difficulties in demonstrating spontaneous transfer on distant analogies sharing mainly structural similarity (e.g., [Gick and Holyoak, 1980](#)), but later studies found a higher degree of spontaneous transfer when more obvious superficial similarity was shared between source and target. Analogical transfer ([Seifert et al., 1995](#)) or environmental cues triggering the retrieval of previously unretrieved relevant information or schemas (e.g., [Yaniv and Meyer, 1987](#); [Langley and Jones, 1988](#)) have been proposed as a cause of incubation effects several times. These prepared-mind theories have proposed various standard or non-standard cognitive mechanisms to explain why the environmental cues are noticed so that spontaneous transfer or retrieval can occur. These explanations include non-focal attention mechanisms ([Olton, 1979](#)), the encoding of so-called “failure-indices” in memory ([Seifert et al., 1995](#)), indexing and differential trace strength ([Langley and Jones, 1988](#)), and initial sub-threshold activation that is raised above threshold by external cues ([Yaniv and Meyer, 1987](#)).

Fixation-Forgetting

Another important theory of incubation explains incubation effects in terms of the creator forgetting fixating elements that prevent them from reaching a solution at first ([Smith, 1995](#)). [Smith \(1995\)](#) argued that incubation effects are caused by competing responses to a problem, which blocks the solution from being reached. These blocks lead to fixation, or “mental ruts”. Active work in trying to reach the solution only activates the blocker further. Following an impasse, there is a shifting accessibility of fixating elements and target (solution), with the target information increasing in relative accessibility to the fixating elements, thereby increasing the probability that the solution is reached when the creator returns to the problem. In other words, the fixating elements are forgotten upon returning to the problem. [Smith \(1995\)](#) also proposed that if the fixating elements were related to the context, contextual shifting—in addition to forgetting—during incubation may improve performance.

Conscious Work

One simple theory is that incubation effects are due to more conscious work (so-called “conscious recurrence”) done from time-to-time on the problem during incubation, which is later forgotten (e.g., [Woodworth and Schlosberg, 1954](#)).

Problem Space Forgetting

[Simon \(1966\)](#) hypothesized that incubation effects were due to selective forgetting. Using problem space theory, he hypothesized that, during problem solving, a goal tree is constantly being constructed and updated in the short-term memory at the same time as information about the problem environment is being familiarized and stored in the long-term memory. If the problem solver leaves the problem for a while (following impasse), the goal tree is quickly forgotten. If they later return to the problem, they will start off with only a higher-level goal (the finer details about the goal tree having been forgotten), but with better problem environment familiarization. Using this information, the new problem-solving session may, therefore, take new routes in the problem space and potentially quickly solve the problem.

Fatigue Dissipation

The fatigue dissipation theory simply holds that the pre-impasse active problem solving is very demanding work, and spending time away allows you to become rested and refreshed so that you will do better the next time you engage the problem. In addition to merely relieving fatigue, it has also been suggested that sleep may restructure new memory representations.

Low Cortical Arousal

Embodied theories of incubation have hypothesized the importance of arousal in incubation. [Martindale \(1990\)](#) proposed that creativity requires remote associative thought, which is best accomplished by defocused attention and a low state of cortical arousal, since this enables a large number of mental representations to be activated at the same time. Thus, a high state of cortical arousal (e.g., when engaging in the draining active search for solutions) may hinder problem solving because remote associations are weeded out by a narrow focus of attention. Setting the problem aside, therefore, increases the chances of creative discovery through lowered arousal levels, leading to defocused attention, which allows for remote associations (see Remote Associates).

Empirical Evidence of Incubation Effects

The extraordinary leap in problem solving, from seemingly conscious inactivity to sudden and surprising insight, is so impressive that it seems to suggest that the act of setting the problem aside somehow facilitated the problem solving (Olton, 1979). It is this alleged performance-enhancing feature of setting the problem aside that incubation researchers have focused on. Historically, the first published experimental study testing incubation defined it as “the spontaneous recurrence from time to time of an idea with more or less modification, while the subject is thinking of other topics” (Patrick, 1937, p. 81). The operational definition of incubation later changed to “laying a problem aside as a step toward solution” (Woodworth and Schlosberg, 1954, p. 838), which stresses the performance improving aspect of incubation. Later operational definitions on the incubation phenomenon have agreed that what needs to be explained is this performance improvement aspect of laying the problem aside, and it is now referred to as the “incubation effect” (see Problem Solving).

The theory that setting a problem aside for a while should improve performance is surprising, given what we know of human cognition and working memory, in particular. Well-known working memory effects, including rapid forgetting due to capacity limitations and fragility to distraction and interference, suggest that in so far as problem solving draws on working memory, it is surprising that putting the problem aside should improve performance. The opposite should be expected—it ought to be better to continue work in order to avoid rapid forgetting processes that occur after setting a problem aside, in part because re-familiarization and re-orientation (“now, where was I?”) with the problem should be required upon returning to the problem.

Experimental Studies

The most typical experimental lab design paradigm applied in incubation studies compares performance on creative problem solving between two groups, only one of which gets an “incubation” break away from active problem solving. The two groups are then compared in terms of their performance in the post-incubation period. Insofar, as the experimental group performs significantly better after the break than the control group, an incubation effect is said to occur.

In a comprehensive meta-analysis of 117 incubation effect studies, Sio and Ormerod (2009) found support for the existence of incubation effects, with a median effect size of 0.26. Their study identified important moderators to this overall effect, including the problem type, length of the preparation period, and the incubation task. Individuals solving creative problems (compared to linguistic or visual problems) were more likely to benefit from an incubation period. Longer preparation periods also gave rise to larger incubation effects. Interestingly, for linguistic problems, engaging in a task that has a low cognitive load (compared to either no task or a cognitively demanding task) during incubation led to the strongest incubation effects. The results thus support the existence of multiple different types of problem-specific incubation effects, as opposed to merely providing support for a singular theory of incubation. It seems that there are several distinct types of incubation effects caused by different mechanisms.

The finding that engaging in a cognitively undemanding task (relatively to a demanding task, rest, or no break) helps creative performance has been further supported in direct experimental tests of the role of mind wandering in incubation. A study by Baird et al. (2012) showed that engaging in undemanding tasks improved performance on the Unusual Uses Test far more than taking a break involving a demanding task, resting, or taking no break. This supports the idea that mind wandering may play an important role in incubation (see Mind Wandering).

The importance of the length of the preparation period shows the importance of the activity taking place prior to incubation in, perhaps, preparing the mind for later opportunistic encounters with chance cues or involvement in repeated problem-solving attempts under fixating conditions. In the meta-analysis by Sio and Ormerod (2009), neither introducing fixating elements nor presenting solution-relevant cues increased incubation effects across studies. However, incubation effects appear to be specific to the individual problem type, and it is possible that facilitating cues and introducing fixating elements only produce incubation effects for certain types of problems.

Accounts that the preparation period in effect functions to prepare the mind for later chance encounters with facilitating cues has received support in studies that utilize insight problems and analogous cues with a similar underlying problem-structure to the incubated problem. A study by Christensen and Schunn (2005) identified that, upon impasse, participants who were uninformed of the relation to the analogous cues more often than chance spontaneously accessed the incubated problem and used the cue to solve the problem. However, other studies utilizing Remote Associates Tests did not find that presenting facilitating cues during incubation increased solution rates.

Conversely, studies testing for the role of fixation in incubation have tended to use associative problems with a single correct answer, such as the Remote Associates Test (RAT). In these experiments, fixation is usually induced before the initial solution attempts at the problems, typically by presenting information that appears to resemble a solution to the problem but which is, in fact, a wrong answer. These studies indicated that incubation effects are likely to occur for people who are fixated. Putting the problem aside for a while, in this case, helps to forget the initially induced fixation that was present during the initial solution attempts. If the fixating elements are context-specific, then changing the context from initial work to the incubated period may also help alleviate the temporary fixating situation. Other fixation studies, however, which have used word completion tests or insight puzzles, have not found that fixating elements were the cause of incubation effects.

Overall, these results suggest that there are several problem-specific types of incubation effects. For creativity problems measuring fluency of production (i.e., the ability to produce multiple responses in a short amount of time, such as the Unusual Uses test), low cognitive load activity during incubation seems to help the production of more ideas post-incubation, which is likely

due to *mind wandering*. For creative problems aimed at finding one correct and remote solution amongst a number of associations (e.g. the RAT), introducing fixating initial elements tends to block the answer, and spending time away may help the creator to forget the fixating elements, leading to the solution (*fixation-forgetting*). However, introducing helpful cues—or even the answers themselves—on RAT problems are not likely to help resolve the problem. Conversely, for creative problems involving complex underlying problem structures, such as insight problems, the pre-incubation solution attempts before reaching an impasse help to mentally structure the problem and prepare the problem solver for later chance encounters with analogous solution elements. In the event the problem solver, by chance, encounters a solution element after having set aside the problem, the structural similarity to the unsolved problem will, at least sometimes, be noticed, and new solution attempts may follow (*facilitating cues*). However, in experiments using RAT problems, facilitating cues do not seem to be very helpful, likely because there is no structural problem pattern that can meaningfully be stored in memory for later recognition in the environment. The problem-specific nature of these distinct types of incubation effects suggest that there is no one correct theory of incubation—several of the incubation theories are, in fact, supported but only for distinct problem types, and these isolated effects often do not seem to generalize to other types of creative problems.

Future Studies

Unlike the historical accounts of incubation in which the problem was voluntarily set aside after reaching an impasse, many experiments testing for incubation effects interrupt the problem-solving process by forcing participants to either stop working on the problem or perform some other task at a time chosen by the experimenter. Following the distinctions between interruption types made by Jett and George (2003), it could be argued that incubation effect studies have typically examined “intrusions” (i.e., an unexpected encounter initiated by another person that interrupts the flow and continuity of an individual’s work and brings that work to a temporary halt). Contrary to intrusions, anecdotal accounts of incubation describe “breaks” (i.e., planned or spontaneous recesses from work on a task that interrupts the task’s flow and continuity, but which entails anticipated or self-initiated time away from performing work). It is, therefore, noteworthy that a majority of incubation effect studies tell us little about incubation conceptualized as breaks. In the domain of human-computer interactions and organizational psychology, it is well documented that—at least on complex tasks—intrusions have a negative effect on performance in terms of how quickly people perform the post-interruption task and the number of errors made. This implies that interrupting will produce some level of disruption so future studies should focus on further understanding the nature of self-initiated breaks away from the problem.

Given that incubation effects appear to be mainly problem-specific, it is important for future studies to test whether individual effects are generalizable across creative problem types. Furthermore, incubation effect studies operate under the assumption of a close relationship between creativity and incubation. However, it is possible that the problem-specific incubation effects generalize to similar non-creative problem types. In order to test for the assumption that the incubation effects are closely related to creative tasks, it is recommended that future studies also include non-creative tasks in their designs. In so far as non-creative problem solving centrally involve working memory, it is to be expected that incubation periods should disrupt problem solving performance (i.e., an inverse incubation effect where working continuously is beneficial). The contrast between non-creative and creative tasks will illustrate whether the incubation effect is specific to creative problems. It is further possible that, as inverse incubation effects are the “norm” on non-creative problems, then even a finding that a break neither disrupts nor benefits performance (i.e., a null effect) for creative problems would be theoretically interesting.

Summary

Anecdotal accounts by eminent artists, inventors, and scientists of the subjective experience of solving creative problems led to the idea that setting the problem aside for a while during an *incubation period* may help inspire its solution. The term “incubation” refers to the theory that unconscious processes may be operating in the period during which the problem solver is not consciously thinking about the problem. Much like an egg ends with the hatching of a bird, incubation sometimes ends in a sudden and surprising insight. However, several other theories have been proposed to explain the incubation phenomenon, including the forgetting of initially fixating elements and a mind prepared to notice facilitating environmental cues during the incubation period. Empirical evidence supports the existence of several problem-specific types of incubation effects. As such, there is no converging evidence for any single theory but, rather, support for several distinct causes of problem-specific effects. Incubation effects, therefore, come about due to a number of different mechanisms, including mind wandering, opportunistic encounters with facilitating cues, and the forgetting of fixating elements that have been preventing the solution.

Innovation

Innovation is viewed as a critical source of organizational competitiveness and important for organizational survival in an increasingly turbulent environment. While researchers have reached consensus regarding the definition of creativity which is a solution, idea, or product that is both novel and useful, the definition of innovation, especially in relation to creativity, is still murky. Many researchers suggest that innovation is defined as the successful implementation of a creative idea. However, some submit that while creativity needs to be truly novel, innovation can be the adaptation of ideas in the current environment (so the idea is novel to the organization, but not completely novel). Others see innovation as a more inclusive term, encompassing both an ideas generation and its implementation. Finally, the most common approach views innovation as only the implementation aspect, excluding the idea generation and development phase (Anderson et al., 2014).

Common to all these definitions is the focus on the implementation of an idea, process, or product. Given the breadth of work devoted to understanding the early processes associated with idea generation, the focus of this article will be on the late processes of idea evaluation, idea selection, and implementation. Idea evaluation and selection are critical for creative problem-solving; in organizational settings, many ideas may be generated, but only a few of the ideas reach the implementation phase (West, 2002). Measurement of this latter stage varies from study to study and can take the form of accuracy of idea evaluation, choice of ideas to implement, and how successful the implementation process was.

Idea Evaluation and Idea Selection

During the idea generation phase, individuals and teams may generate a large number of ideas, especially if they are engaged in brainstorming (West, 2002). However, it is unrealistic that all of these ideas can be used and implemented. In fact, brainstorming rules require participants to suspend evaluation and not judge ideas, and therefore list any and all ideas. As a result, brainstorming and idea generation may result in a large number of ideas that need to be appraised and screened. Mumford et al. (2002) proposed that idea evaluation and selection include three major activities: forecasting possible consequences and outcomes of selecting and implementing an idea; judging how well the characteristics of an idea fit with specific standards and criteria; and choosing, revising, or rejecting the idea as a solution. Relative to the idea generation process, which is seen as mainly divergent in nature, the idea evaluation process is viewed as mainly convergent. However, it is important to note that idea evaluation, similar to other processes of creative thought, includes both convergent and divergent elements. For example, forecasting possible consequences includes a divergent component, as multiple potential consequences need to be thought about. However, judgments regarding how well ideas or solutions conform to specific standards are more convergent. While the research literature on idea evaluation and idea selection is more limited compared to that of idea generation, the research to date provides support for the importance of these processes for creativity and innovation and provides information regarding the factors that influence the application of these processes.

One of the most researched questions regarding idea evaluation is whether individuals and teams can evaluate ideas accurately, and the factors that influence accuracy. Some research suggests that people can evaluate ideas accurately for quality and originality, while other work has found that not all individuals can accurately evaluate ideas. For example, creative individuals tend to be more accurate in their evaluations. In addition, when people are asked to evaluate creativity as an overarching property of the idea, novelty of the idea tends to be a stronger predictor of the evaluation of creativity relative to usefulness, even though both are necessary for a creative idea. Finally, research suggests that participants tended to reject highly original or risky ideas more likely to select ideas that were consistent with social norms, easy to understand, and likely to quickly lead to desirable outcomes, especially under high time pressure.

Importantly, selection and evaluation are separate but related functions. Research that evaluated both idea evaluation and idea selection found that the participant evaluation predicted which ideas were selected. No individuals or teams chose ideas that they

themselves thought were not good ideas (scored high on quality). However, individuals and teams were not always accurate in their evaluations, resulting in the selection of ideas that they thought were good or creative, but that in fact were not so.

The relationship between idea generation and idea evaluation has also been considered. Many models of creative problem-solving suggest that the relationship is somewhat linear, ideas are generated, then evaluated, and individuals and teams potentially can return to idea generation if the results of idea evaluation are unsatisfactory. Early work suggested that engaging in evaluation during the generation phase could be detrimental, which is the foundation for the brainstorming rule of suspending evaluation. Research using artists indicated that the role of evaluation increased during the creative process, supporting this notion.

However, other work concluded that early evaluation may actually increase creativity. [Harvey and Kou \(2013\)](#) found that both may occur. Their work proposed that idea evaluation did not always follow from idea generation, and that in some cases, the two co-occurred. Harvey and Kou suggested that engagement in evaluation processes supports the development of a shared framework for the problem at hand and directs collective attention to ideas to guide feedback and decisions of how well ideas address the problem.

Team Influences on Innovation

Much of the work conducted to understand the factors that influence organizations in adopting innovation has focused on organizational determinants. Teams were studied as a context in which individuals can thrive and be creative ([Reiter-Palmon et al., 2008](#)). Team composition, specifically the diversity of the team, has long been considered an important factor that should facilitate creativity and innovation ([Hulsheger et al., 2009](#)). Early work in the area of team composition assumed that diversity in team composition would be beneficial resulting in increased creative output of teams, as a product of the diverse knowledge and experiences of the team members. In addition, it is expected that team diversity can contribute to the successful implementation of ideas and solutions as diverse teams can anticipate more of the potential obstacles in the implementation process and evaluate ideas more fully ([Reiter-Palmon et al., 2008](#)). However, research suggests that the impact of team diversity is much more complex ([Hulsheger et al., 2009](#); [Reiter-Palmon et al., 2011](#)).

Demographic diversity, that is, diversity based on factors such as age, race, gender, and so on, has not been consistently linked to improved creativity and innovation ([Reiter-Palmon et al., 2011](#)). While some research suggests that demographic diversity is beneficial, other work suggests no effects. Finally, some work found detrimental effects of demographic diversity of innovation. Most of the research on demographic diversity also evaluated each dimension of diversity (e.g., gender, age, race) on its own. Studies that evaluated multiple dimensions of creativity found that creativity and innovation were improved or hindered, depending on the dimension evaluated. To address these different results, several studies discovered that when team members and leaders valued diversity, diverse teams were more creative. These findings indicated that perceptions about the role and importance of diversity for creativity may also shape the effect that team diversity has on creativity.

In contrast to demographic diversity, differences based on attributes that are relevant to job performance, such as diversity in education, function in the organization, and job relevant knowledge, skills, and abilities, that is, functional diversity, were more likely to influence team creativity ([Hulsheger et al., 2009](#)). Research evaluating functional diversity found positive effects for functional diversity, suggesting that teams comprised of members from different and diverse functional backgrounds outperform homogeneous teams in terms of creativity and innovation.

The importance of functional diversity for innovation is in the breadth of informational and knowledge resources that different team members bring ([Reiter-Palmon et al., 2008](#)). However, in order to be able to use this information and knowledge, team members must be able to share the information and the team must be able to capitalize on the shared knowledge. As a result, it is not surprising that group processes that facilitate positive interactions, managing conflict effectively, psychological safety, and openness were particularly effective in enhancing innovation ([Reiter-Palmon et al., 2011](#)). Research suggests that team goals that emphasized collaboration and cooperation were related to new idea generation.

Communication, especially open communication, was also important for innovation. A meta-analysis by [Hulsheger et al. \(2009\)](#) found that internal communication was positively related to team creativity and innovation. In addition, the nature of the communication was important. Collaborative communication was related to higher creativity and innovation, whereas contentious communication was related to lower creativity and innovation. Psychological safety, which is defined as the shared belief that it is safe for individuals within the team to take interpersonal risks, also been facilitated effective and positive communication. Psychological safety was related to discussion of new ideas, making suggestions, idea generation, and importantly, to effective implementation of new ideas. West and his colleagues researched psychological safety in a series of studies across different industries and team types. Psychological safety was an important predictor of team innovation. However, a meta-analysis by [Hulsheger et al. \(2009\)](#) found that while psychological safety was predictive of team creativity and innovation, the relationship was weak.

Organizational Influences on Creativity

Organizational climate in particular has received attention as a contributing factor for innovation. [Hunter et al. \(2007\)](#) found that most frameworks included common dimensions such as positive relationships with peers, support from top management, challenge, autonomy, intellectual stimulation, and support for risk-taking. Similarly, a meta-analysis conducted by [Hunter et al. \(2007\)](#) concluded that these climate dimensions were related to creative performance of individuals and teams in the organization.

Further, the strongest climate dimensions were those related to having positive relationships, intellectual stimulation, and challenge. The importance of positive relationships is not surprising given the importance of social processes such as information sharing, communication, and trust for creativity and innovation. Intellectual stimulation and challenge speak to the importance of cognitive factors. Together, these findings indicate that a work environment in which people are presented with meaningful and challenging work and that allows for the exchange of thoughts and ideas is critical for creativity and innovation.

Leaders have long been viewed as important creators and transmitters of organizational climate. Leaders can help in facilitating more effective discussions, creating positive team interactions, which would lead to increased trust and psychological safety, which in turn will lead to improved communication and information exchange within the team. In addition, an important role for the leader in supporting innovation is removing obstacles—such as providing information, resources, administrative support, clarity, as well as serving as a champion for innovation. Leaders can also support innovation by facilitating workflow, work assignments, and autonomy, which have been linked to climate for innovation (Hunter et al., 2007).

Another important organizational factor that can influence innovation is resources. When discussing resources, it is important to note that a variety of resources should be considered. These resources include materials and funds, infrastructure and facilities, personnel quality and quantity, and time. The development and implementation of new ideas is time-consuming and can be expensive in terms of personnel, material, and time. Therefore, the availability of resources is likely to influence creativity and innovation.

Resource availability, especially financial resources, is related to adoption of innovation and innovative project success. Slack resources may facilitate creativity and innovation by allowing for experimenting, risk-taking, and working on multiple promising projects simultaneously. Slack resources also allow organizations to better prepare for changes in the environment and respond more successfully with innovation. However, while organizations that have resources available may be able to experiment and take risks, these organizations may be reluctant to do so.

On the other hand, resource constraints may facilitate creativity as organizations need to find creative ways to address problems while lacking resources. Specifically because they lack the resources, these companies must respond creatively and quickly to market and external forces to survive.

These contrasting findings suggest the possibility of a curvilinear relationship between resources and creativity. That is, slack resources will result in the organization not willing to develop and implement creative ideas as these are risky, or having too many ideas that are being developed. However, scarce resources will result in the organization not being able to develop and implement creative ideas due to limited funds and personnel. It is therefore important for organizations to evaluate what resources are available. On the one hand, too few resources may lead to difficulty in developing creative ideas, while too many resources may result in the development of many ideas, but ones of limited creativity.

Finally, organizational strategy is an important consideration, especially for the type of innovation that is pursued. Specifically, organizations can engage in exploration or exploitation (March 1991). Exploration is defined as the search for new ideas and products, developing new capabilities and is associated with risk-taking, experimentation, and flexibility. Exploration on the other hand is defined as refinement, implementation, and execution and is associated with capitalizing on known strengths of the organization. Research suggests that both strategies are important for innovation and organizational survival. However, exploration and exploitation have been associated with different kinds of innovation. Exploitation, due to its focus on exploiting current strengths, tends to be associated with incremental innovation, whereas exploitation, which focuses on searching for new capabilities, tends to be associated with radical innovation.

An important issue in the discussion of exploration and exploitation is whether these are two competing strategies or complementary ones. As both require investment of resources, some argue that organizations will be required to choose which strategy to use. However, organizational innovation and survival may be improved when both strategies are pursued simultaneously, noting that approach as ambidexterity (Zacher et al., 2016). Organizations, and leaders, that are able to manage this tension or paradox, by excelling in both exploration and exploitation, are more innovative.

Conclusion

Innovation is typically considered the criterion in most studies. While empirical research has looked at the effect of individual creativity and its effect on team creativity and innovation, only limited empirical work is available on the consequences of innovation. Much of that research focused on the organizational and financial consequences of innovation such as new products, increase in market share, and organizational adaptation and survival. It is therefore critical for researchers to also evaluate the outcomes of innovation for organizational survival and growth, as well as outcomes related to individuals and teams within the organization.

Insight in Problem Solving

Over the last 40 years, there has been a resurgence of interest in the notion of insight in creativity. The concept of insight in thinking was introduced by the Gestalt psychologists, early in the 20th century, in response to Thorndike's studies of habit formation in animals (Scheerer, 1963). Thorndike proposed that all behavioral advances came about through laborious trial and error, as the animal, starting with random responses, gradually worked out the sequence that would enable it to obtain food.

The Gestalt psychologists responded to Thorndike's theorizing by proposing that animals—and, by extension, humans—could solve problems through *insight*, on the basis of an understanding of the overall structure of a situation. In a famous series of studies, Köhler demonstrated that chimpanzees could produce complex solutions to problems, sometimes suddenly, as integrated wholes, without first working things out through "blind" trial and error. In the Gestalt view, if a problem was understood fully, then the thinker could produce a novel response that was not dependent on experience. For example, some of Köhler's chimps produced novel solutions to problems that were not related in any simple way to their experiences in similar situations. Wertheimer drew similar conclusions from studies of the performance of children on problems of various sorts.

Gestalt Theory

Gestalt theorizing about creative thinking was based on an analogy to perceptual processing. The sudden appearance of a complete solution to a problem was assumed to be brought about through mechanisms comparable to those underlying perception of a reversible figure, such as the reversible cube. The reversible cube suddenly switches from one interpretation, or structure, to another, as the person examines it. In a problem situation, also, more than one structure was possible. A problem existed because the person had structured the situation in a way that made solution unobtainable. In order for solution to occur, the person had to relinquish the initial analysis of the situation, which might allow a "re-structuring" to occur, which could bring about a new approach to the problem, and solution.

The core of the Gestalt analysis of thinking was the distinction between *reproductive* and *productive* thought. Reproductive thought, called *analytic thinking* by modern researchers, is based on the application of knowledge to a new situation. It might, in some circumstances, be successful. However, reproductive thinking could also result in the application of knowledge to a situation in which it did not fit, producing failure and impasse.

In order to deal with situations demanding true advances in thinking, it was necessary to put aside the past, and analytic thinking, and turn to productive thinking. Application of productive thinking to a problem involved several steps. First, reproductive thinking brought about a series of failures. Those failures would ultimately lead to an impasse, as the person exhausted possible solution methods based on reproductive thought. The occurrence of an impasse could serve to trigger a sudden restructuring of the

problem, resulting in a new perspective coming to mind. In the Gestalt analysis, restructuring was something that *happened to a person*, in a passive way, as the interpretation of the problem changed suddenly, in an Aha! experience. That restructuring was spontaneous, since it was out of the person's control. Again, the mechanism involved in restructuring a problem was assumed to be analogous to that which brought about spontaneous restructuring in perception.

The series of events that occurred when solving a problem through insight can be called the *insight sequence*:

problem $\Rightarrow$ impasse $\Rightarrow$ restructuring $\Rightarrow$ insight

It is still a critical component of modern formulations of Gestalt theory.

Classical Research in Support of Gestalt Theory

The emphasis on the need to relinquish the initial interpretation or structure of a problem, and replace it with a new one, served as the basis for a series of studies carried out by the Gestalt psychologists (Scheerer, 1963). Wertheimer studied insight in children, examining how his participants went beyond old methods, and moved to new interpretations of problems. Duncker carried out investigations of the thought processes involved in problem solving. He is best known for his research on *functional fixedness*, the demonstration that habitual uses of a common object can interfere with using it in a novel way in order to solve a problem. The most well-known of his investigations examined the candle problem, in which a candle must be affixed to the wall. An effective solution, one that is proposed infrequently, is to use a small cardboard box, which initially is holding tacks, as a shelf or candle holder. If the box is presented empty, it is frequently used, but presenting it filled with tacks interfered with that novel use. Maier also carried out several studies in which productive thinking was demanded. The most well-known of those studies centered on the two-string problem, in which the participant must tie together two out-of-reach strings. In Maier's analysis, the solution resulting from productive thinking involved constructing a pendulum, using a common object as the weight for the pendulum.

The strongest demonstration of the potential dangers in relying on experience to deal with the present was seen in the studies of mental set, carried out by Luchins and Luchins. In those studies, participants were presented with a series of mathematical problems, all of which were solved with the same relatively complex solution (*set* problems; all solved with the *set* solution). A series of *critical* problems were then presented, all of which were similar in appearance to the set problems. The critical problems could be solved using the set solution, but could also be solved using a much simpler *direct* method. Naïve participants, not exposed to the set problems, almost always solved the critical problems quickly, using the direct method. In contrast, participants with success solving the set problems solved the critical problems using the complicated solution, and were sometimes unable to solve a simple problem, to which the set solution did not apply. Experience with the set solution had blinded them to other methods, which naïve individuals saw immediately.

In sum, Gestalt theory argued that insight was the result of productive thinking. Insight came about as a result of relinquishing a reliance on experience, and organizing one's knowledge in new ways, to deal with the demands of a novel situation.

Development of Interest in Insight

Throughout most of the 20th century, Gestalt theory was not a dominant influence in psychology. Insight was typically included in discussions of thinking, but it was peripheral to, rather than a core component of, analyses of problem solving. An article by Scheerer (1963) in *Scientific American* can be seen as an attempt to bring Gestalt theory in general, and the notion of insight in particular, to the attention of researchers. However, Scheerer's article was not frequently cited until around 2000, when its citation rate almost quadrupled; and it has stayed at that level. What, then, explains the surge of interest in insight over recent years? That development can be traced to several studies, which raised questions about the usefulness of insight and restructuring as explanatory concepts in the analysis of thinking, and which tried to bring those concepts under the umbrella of mainstream experimental psychology. That critical discussion stimulated broad interest in the issues central to the Gestalt psychologists' analyses of thinking, with its focus on productive thinking, restructuring, and insight. Researchers supporting the Gestalt view responded to those challenges, by developing modern variations on Gestalt theory—*neo-Gestalt theory*—and providing experimental support for the neo-Gestalt views. The next several sections trace the historical development of those events.

Challenges to Gestalt Theory

In one study raising questions about insight, Perkins (1981) analyzed performance on the Antique Coin problem.

A stranger approached a museum curator and offered him an ancient bronze coin. The coin had an authentic appearance and was marked with the date "544 B.C." The curator had happily made acquisitions from suspicious sources before, but this time he promptly called the police and had the man arrested. Why?

This problem is an “insight” problem, presumably solvable only through restructuring and insight. An “analytic” problem, in contrast, is solvable through the direct application of one’s knowledge. In order to solve the Antique Coin problem, one must switch perspectives, away from that of the curator, to that of the person making the coin. How could the coin-maker have known that Christ would be born *544 years in the future*? The coin must be fake, and the man is a swindler. Perkins reported that “insight” into the solution came about as the result of the individual’s realizing the contradiction in the coin’s having the date “B.C.” printed on it. That realization was based on analytic thinking—the application of the person’s knowledge and reasoning ability to the situation. Sometimes a person *recognized* that contradiction, in a single step, a small-scale “leap of insight.” In other cases, the contradiction was *reasoned out*, in a brief series of steps. Perkins concluded that the insight process did not carry out a large amount of thinking, and that it was essentially equivalent to a few steps of reasoning. That conclusion raised problems for the Gestalt idea that insight was a special process, resulting in a far-ranging leap into the unknown, independent of such processes as knowledge and reasoning.

A second challenge to Gestalt theory came from a study by Weisberg and Alba (1981), which examined performance on the 9-Dot problem. The person is shown a 3×3 matrix of dots, and is asked to connect all the dots, using four connected straight lines; that is, without lifting the pencil from the paper. According to the Gestalt view, the problem was, in principle, not very difficult, since we can all draw four connected lines. However, the problem is, in fact, extremely challenging, with almost no one able to solve it. In the Gestalt view, the problem’s difficulty arose from the perceptual configuration of the problem: people were fixated on the square shape of the matrix, and kept their lines within the boundaries of the square. That restriction, not stated in the problem, but assumed by the participants, made the problem impossible to solve. According to the Gestalt analysis, if that restriction could be eliminated, the problem should become easy.

Weisberg and Alba tested that prediction, and those results also did not support the Gestalt view. Participants were told that, in order to solve the problem, they had to draw lines outside the boundaries of the square. That instruction resulted in people going “outside of the box,” but only a small minority of them solved the problem; and those who did, worked incrementally toward solution, rather than having things suddenly fall into place, as the notions of spontaneous restructuring and insight would lead one to expect. Weisberg and Alba concluded that the 9-Dot problem was difficult because it demanded sophisticated knowledge, which most people did not possess. They also argued that the notion of insight might not be useful in explaining how solution came about, at least in the context of the 9-Dot problem.

That pessimistic view on insight was extended by MacGregor, Ormerod, and Chronicle (2001), who proposed that the difficulties in solving the 9-Dot problem were the result of heuristics adopted by the problem solver. The problem is unsolvable because most people are unable to anticipate or imagine the negative outcomes of drawing all the possible series of lines that stay within the square shape, so they continue doing so. Their capacity for “lookahead,” related to visual working-memory (WM) capacity, is too small. It has been demonstrated that WM capacity may play a role in solution of the 9-Dot problem, which supports the perspective of Chronicle and colleagues.

Based on those experimental results, and their interpretations, a distinction was made, between insight as a *special process*—the Gestalt view; insight as the result of spontaneous restructuring—and insight as *business as usual*—insight as the result of analytic or reproductive thinking. Both Perkins and Weisberg and Alba can be seen as advocating the *business-as-usual* view. Presentation of the *business-as-usual* view stimulated several different types of responses from researchers supportive of the Gestalt view. First, research was carried out to demonstrate that there were explicit differences between the processes underlying productive thinking that results in insight, and those underlying reproductive or analytic thinking. That is, attempts were made to demonstrate the *special-process* nature of insight. Second, theorists attempted to make explicit the differences between Gestalt theory and the *business-as-usual* interpretation of insight. The classical Gestalt view was reformulated, into what one can call *neo-Gestalt* theory.

Responses to the Challenges to Gestalt Theory: Research Supporting the Special-Process View

A number of different types of evidence have been brought forth in support of the Gestalt view (for review, see Weisberg, 2020). In a seminal set of studies, Metcalfe presented evidence to support the notion of two modes of solving problems, insight versus analysis. Her studies were designed to show that insightful solutions of problems, arising, presumably, from a sudden restructuring of the problem situation, were brought about differently than solutions based on analysis. Those latter solutions presumably came about as the result of the application of one’s knowledge to a problem, and the use of that knowledge to gradually work out a solution. Metcalfe had people provide ratings of how *warm* they were—how close to the solution they felt they were—as they worked on insight versus analytic problems. Warmth ratings for solutions to analytic problems increased gradually, but warmth ratings for solutions based on insight stayed at a low level until just before the problem was solved, when they quickly moved to the maximum. Those results were taken as evidence that insight was the result of a sudden change in how the problem was perceived—a restructuring of the problem—which supported the Gestalt *special process* view.

Another demonstration of the difference between analysis and insight as modes of thinking was produced by Schooler, Ohlsson, and Brooks. They had individuals think aloud while trying to solve analytic versus insight problems, and they found that verbalization interfered with solution of insight problems, but not analytic problems. The results were taken as evidence that insight was brought about by processes that are not verbalizable, i.e., outside the domain of conscious analytic thought. Similarly, Gilhooly and Murphy (2005) gave individuals a group of analytic and insight problems to solve. Insight problems and analytic problems

each tended to be solved together, which was taken as evidence that different processes played a role in solution of the two types of problems. Further evidence in support of the analysis-insight distinction was the finding that solutions accompanied by an Aha! experience are more likely to be correct than are answers not accompanied by an Aha! It was proposed that solutions arising from insight bring with them subjective elements, including perhaps a feeling of confidence, as well as feelings of closure and pleasure, which might lead the individual to the belief that the solution must be correct, before verifying it and before feedback is given.

Going beyond traditional methods of studying problem solving, Kounios and Beeman (2015) and their colleagues have used neuroscience methods to demonstrate differences in the processes underlying insightful versus analytic solutions to problems. They examined performance on compound remote associates (CRA) problems, in which three words are presented, and the individual is asked to find a fourth word that will combine with each of the other words in a compound word or phrase. Here is an example problem.

Given these three words: *work, wise, tower*, find a fourth word that will combine with each of those words, to make a compound word or familiar phrase.

The answer is *clock*: clockwork, clockwise, clock tower. An important aspect of CRA problems is that people report solving them in two ways: incrementally, or in a burst of insight. That result means that the same type of problem can provide information concerning the brain processes underlying analytic thinking versus insight. Kounios and Beeman reported several differences in brain processes underlying solutions through insight versus analysis, and concluded that there are significant differences between those processes. In addition, they reported that certain patterns of brain activity can predict if a person will solve a not-yet-presented problem with insight.

Still another attempt to demonstrate the difference between insight and analytic thinking is seen in the work of Wiley and her colleagues (e.g., Wiley and Jarosz, 2012), who proposed that insight differs from analysis in terms of the involvement of working-memory (WM). Analytic thinking, which depends on application of knowledge to a problem, and planning out the solution, would seem to put demands on WM. Insight, in contrast, comes about as a break from planning and analytic thinking, and so would seem to be independent of WM. Wiley and colleagues presented evidence for the lesser involvement of WM in solution of insight problems.

The research just reviewed is a sample of the sorts of studies carried out by supporters of the Gestalt view. Those various research projects were accompanied by attempts to expand classical Gestalt theory, to deal with the challenges raised by researchers critical of the insight view. Attempts were made to make the theory more amenable to empirical test, as well as to make more specific the differences between the role of insight versus analysis in thinking.

Neo-Gestalt Theory

Ohlsson's Representational Change Theory

In emphasizing the *special-process* aspect of insight, Ohlsson (2011) pointed to the importance of restructuring and insight as nothing less than a factor in our survival as a species. The world is in a state of unpredictable, large-scale, flux. Therefore, "experience is guaranteed to be misleading most of the time" (Ohlsson, 2011, p. 21). Ohlsson proposed that the mechanisms of *deep learning* have evolved to deal with that quandary. Deep learning makes it possible for us to:

abandon, override, reject, retract or suppress knowledge that we had previously accepted as valid in order to track a constantly shifting and fundamentally unpredictable environment and thereby indirectly create mental space for alternative or even contradictory concepts, beliefs, ideas and strategies. (p. 21)

One mechanism of deep learning is problem solving through insight, achieved through the already-familiar *insight sequence*. Ohlsson's theory is called *Representational Change Theory* (RCT), because the critical component in insight is restructuring the situation, that is, changing the representation of the environment.

RCT has undergone several iterations. Ohlsson (1992) originally proposed a set of three "switch when stuck" heuristics to account for the occurrence of insight. One is trying to *switch* the problem representation, because one is *stuck*. The restructuring heuristics were the following.

- (1) *Elaboration*: the individual examines the situation to determine if there is overlooked information or object(s) that could be used in a new type of solution.
- (2) *Re-encoding*: the individual analyses the situation, in order to determine if there is a new way of thinking about any object.
- (3) *Constraint relaxation*: the individual attempts to change the representation of the goal.

The second version of RCT, Ohlsson (2011, ch. 4, 11) proposed that representational change came about as the result of *redistribution of activation* in semantic memory. Ohlsson assumed that any problem will activate representations of differing strengths, based on experiences in similar situations. The strongest of those representations will control the behaviors that are produced.

In situations that demand creative thinking, that initial representation, based on the past, will result in failure. Each time a solution results in failure, it produces negative feedback for the representation. If those failures continue, in an impasse, the initially-dominant representation will be replaced by one of the other possible representations. The person will then look at the problem differently, in a restructuring, which may result in a new class of solutions. That analysis of restructuring in problem solving is similar to the Gestalt psychologists' notion of the "spontaneous" reversal of a reversible figure. Restructuring comes about as the result of processes not under the conscious control of the person.

In the newest version of RCT (Ohlsson, 2018), representational change can occur without failure and impasse. If information from the environment does not match expectations, it may force a change in the analysis of the situation. Since experience cannot be helpful at that point, Ohlsson proposed that semantic analysis of the problem can result in a new structure.

Other Neo-Gestalt Views

Other researchers have developed neo-Gestalt views, which build on classic Gestalt theory, and are similar to Ohlsson's RCT. Perkins (2000) proposed the need for *breakthrough thinking* in problem solving, because many problems do not yield to analytic thinking, which is based on reason. Those problems are *unreasonable*, and demand that one break away from analytic—"reasonable"—thinking, and search in other ways for new ideas. A similar view was presented by Wiley and her colleagues (e.g., Ash et al., 2009; Danek et al., 2018; Wiley and Jarosz, 2012), who made a categorical distinction between analysis and insight. Similar to other neo-Gestalt views, Wiley and colleagues argued that the critical shortcoming of analytic thinking is that there are problem situations in which it is not useful. In order to progress, the thinker must reject analytic thinking, and re-structure the situation: "[R]estructuring is a mechanism that cannot be accommodated by classic heuristic search accounts of problem solving, and requires an additional theoretical framework" (Ash et al., 2009, p. 8).

Thus, theories of problem solving must include a mechanism—restructuring, a special process—that goes beyond analytic thinking. A similar viewpoint was proposed by Kounios and Beeman and their colleagues (e.g., 2015), who also emphasized the close relationship between creative thinking, restructuring, and insight.

Insight and Creativity in Neo-Gestalt Theory

Insight and creativity are closely linked in the neo-Gestalt views. According to Ohlsson (2011) and Perkins (2000), if an advance does not come about through insight, it is not creative. Similarly, Wiley and Jarosz (2012) dichotomized analytical problems (such as verbal mathematics problems) and "creative" problems, that is, problems that must be solved through insight. Wiley and Jarosz do not consider the possibility that insight ("creative") problems could be solved through analytic thinking. However, recent research has found that analytic thinking can bring about solutions to insight problems.

Analytic Thinking in Solving "Insight" Problems

Fleck and Weisberg (2013) examined people's performance on several insight problems, and found that analytic thinking brought about solutions to "insight" problems, including solutions based on restructuring. Fewer than 10% of the solutions were the result of the full insight sequence. Those results raised questions about whether insight and analysis are different processes. Most of the solutions in Fleck and Weisberg's study were based on heuristic methods, of several sorts. That finding contradicts the proposal just quoted, that restructuring in problem solving cannot come about through heuristic methods.

An Integrated Model of Insight

In response to their results, Fleck and Weisberg (2013) proposed a model of problem solving that incorporated analysis *and* insight as components. That model attempted to provide an integrated view of a wide range of results from problem-solving research. The model, presented in Fig. 1, assumes that the first stage in problem solving, as in all cognitive processes, involves an attempt to match the problem with information in memory. If there is information in memory that is relevant to this particular problem (Stage 1A—Positive match), then a possible solution will be brought to mind, and the person will attempt to transfer that old solution to the current problem. If that transfer is successful (Stage 1B—Success), the problem is solved (Stage 1C). If transfer fails, but new information arises out of that failure (Stage 1D), then the person searches memory again, with the possibility that a new method will come to mind (recycling through Stage 1A). Critically for the present discussion, restructuring of the problem may occur at this point in the process; new information that has arisen from failure may bring to mind a new way of analyzing the problem. This restructuring can be called "top-down" restructuring: it uses the person's knowledge to deal with any shortcomings in the failed solution.

If a method tried at Stage 1 fails, and no additional information arises from that failure, the person goes to Stage 2, and attempts to apply heuristic methods to the problem. Examples of heuristic methods would be logical analysis of the information in the problem; attempting to apply mathematical methods to the problems; using means-ends analysis or hill-climbing; or trial-and-error. If one of those methods works, the problem is solved (Stage 2C). If new information arises out of a failure of a heuristic method (Stages 2B and 2D), that can produce another "top-down" restructuring, and another search of memory (Stage 2E).

STAGE 1 – MATCHING A PROBLEM WITH KNOWLEDGE

STAGE 2 – APPLYING HEURISTICS TO A PROBLEM

STAGE 3 – RESTRUCTURING HEURISTICS IN RESPONSE TO IMPASSE (BOTTOM-UP RESTRUCTURING)

Figure 1 Problem solving model (Stages 1–3).

That search can result in a new solution method being retrieved (Stage 2F). This would be another example of restructuring arising from a failed solution attempt.

An important point to take away from the discussion of analytic thinking in stages 1 and 2 of the model in **Fig. 1** is that analytic thinking is an *active* process. The individual is constantly receiving new information, in feedback from the environment, which can significantly change the situation, and produce responses that are totally different from where the person might have begun.

If there is no solution, and no new information from Stage 2, then the person is at an impasse, and goes on to Stage 3, where the restructuring that is the focus of the neo-Gestalt theorists may come about. [Ohlsson's \(1992\)](#) three restructuring heuristics—*elaboration*, *re-encoding*, and *constraint relaxation*—are incorporated in Stage 3. Several of [Fleck and Weisberg's \(2013\)](#) participants went through those heuristics upon reaching impasse, so there is empirical support for their inclusion in models of insight. Those restructuring heuristics can produce result in “bottom-up” restructuring: it comes about through an examination of the objects in the problem, without any overarching plan as to how the problem might be re-structured. That sort of processing would be expected if a person is at impasse.

In sum, the model outlined in [Fig. 1](#) provides a framework that can serve as the basis for integrating analysis and insight into an overarching scheme for understanding problem solving. However, the study of insight is at present an area in which much research activity is taking place. Therefore, it is premature to conclude that anything like closure has come about in this area. This discussion will conclude with an examination of a number of issues that are the subject of debate.

Insight: Some Remaining Questions

How Important Is Insight in Creative Thinking?

Researchers' interest in insight is based on the assumption that insight is critical in our dealings with the world. However, until relatively recently, that assumption has not been explicitly tested. [Beatty et al. \(2014\)](#) examined directly the relationship between insight and creativity. In two studies, with large samples of undergraduates as participants, they found no relationship between solving insight problems in the laboratory and real-world creative achievement. Undergraduates, because of their limited opportunities, might not be the best population in which to study creative achievement; however, the results still raise questions for the idea that insight is the core of creative thinking.

On Executive Functioning in Insight

[Wiley and Jarosz \(2012\)](#) and their colleagues proposed, based on neo-Gestalt theory, that a high level of executive functioning has negative effects on insight. Research by [Chuderski and Jastrzebski \(2018\)](#) demonstrated that executive functioning was important in insight, which contradicted the neo-Gestalt view, and provided support for the analytic view. A large number of participants were given a set of insight problems to solve; as well as tasks testing logical reasoning and aspects of working memory, as measures of executive functioning. Insight performance was very closely related to measures of executive functioning, indicating that the two constructs might be closely related, or even identical. Other research has supported the conclusion of Chuderski and Jastrzebski.

Thus, research concerning the possible role of executive functioning in insight produced conflicting results. Some studies showed that executive functioning has a positive relationship with problem solving through insight. Other research supported the opposite view, that executive functioning is negatively related to insight, or not related at all. DeCaro and her colleagues (e.g., [DeCaro, 2018](#)) proposed that the role of executive functioning in problem solving depends on the specific details of the problem being worked on. If a problem is complex, making it difficult to understand the instructions and, therefore, to create the problem representation, then high levels of executive functioning should be helpful. If a problem is not complex, then all individuals, irrespective of level of executive functioning, should be able to formulate the initial representation.

DeCaro and others assumed that, once an impasse has been reached while trying to solve a problem, restructuring and insight come about through processes that are independent of executive functioning. In contrast, the integrated model of problem solving discussed earlier leads to the expectation that executive functioning would be important in insight. The *switch when stuck* heuristics, that play a role in stage 3 of the model, would seem to require executive processes, first to develop solution methods for a given problem, and then to carry them out. There are still some questions to be resolved concerning the role of executive functioning in insight.

The Aha! Experience as the Defining Characteristic of Insight

The Gestalt psychologists argued that the critical role in insight is restructuring the problem representation (e.g., [Scheerer, 1963](#)). There has been a movement recently toward an emphasis on the *Aha!* experience itself, rather than restructuring, as the defining feature of insight. [Bowden and Grunewald \(2018\)](#), for example, proposed that, to study insight, researchers should concentrate on situations where an *Aha!* occurs. However, using *Aha!* experiences to define insight might lead to problems for researchers, because one can have an *Aha!* experience in situations having nothing to do with creative thinking. As one example, the experience that can accompany the sudden recall of a previously irretrievable name—resolution of a “tip-of-the-tongue state”—may be indistinguishable from the *Aha!* that accompanies sudden solution of a problem. If so, defining insight in problem solving may require more than determining the presence versus absence of the *Aha!* experience. Here is another area where more research is called for.

Insight versus Analysis: Different Philosophies Concerning Creativity

Neo-Gestalt theory takes a two-pronged perspective on creativity. It is assumed that individuals are capable of productive thinking. However, people often fail to think productively, because of factors that conspire against it. Those factors include the large-scale changes in the world, that make it resistant to transfer of knowledge; as well as smaller-scale aspects of problems, that work against using productive thinking to deal with them. The analytic viewpoint, in contrast, assumes that the world is typically receptive to the transfer of knowledge. If that were not true, it would be hard to understand why organisms have developed the capacity to remember the past.

In discussing analogical transfer, Gentner proposed the “kind world” hypothesis, which assumed that things in the world are often what they appear to be (Gentner and Maravilla, 2018). That is, if something looks very much like a tiger, it may very well be a tiger. Therefore, applying one’s knowledge to the world is, in most cases, a useful way of dealing with issues that arise in our interactions with the environment. Attempting to use the past as the first step in dealing with the present, combined with the active nature of analytic thinking (see Fig. 1), can sometimes be the basis of creative advances.

Those differing philosophies motivated different sorts of approaches to the study of problem solving and creativity, which have resulted in disagreements over interpretation of research results. In addition, research in recent years have resulted in large-scale differences in theoretical analyses brought forth to place specific research results into a broader context. The last few decades have brought an acceleration of research in the study of insight, broadly construed, and there are no signs of a lessening of interest in this area. The future promises to bring increases in understanding of this central aspect of human cognition.

Introduction

In his novel *Doctor Zhivago*, Boris Pasternak described an episode of inspiration:

After two or three stanzas and several images by which he was himself astonished, his work took possession of him and he experienced the approach of what is usually called inspiration. At such moments the correlation of forces controlling the artist is, as it were stood on its head. The ascendancy is no longer with the artist or the state of mind which he is trying to express, but with language, his instrument of expression. (1961, p. 427)

This passage captures the hallmark features of inspiration: passive evocation (“his work took possession of him”), transcendence (“the ascendancy”), and an impulse toward expression (“language, his instrument of expression”). Echoing other creators before him (Clark, 1997), Pasternak’s account poses a perennial but controversial thesis: inspiration is a central force in the creative process.

Traditionally, scholars portrayed inspiration as a mystical phenomenon outside the scope of science. In ancient Greece, Plato described poetic inspiration as divine madness, a possession by the Muse that imbues the poet with a vision of beauty and truth. By the 17th century, inspiration was predominantly discussed in the context of religion, where the Bible was professed to be the gateway to divine revelation (Lowth, 1971). In the 18th century, the focus shifted to unconscious sources of inspiration that are within the person but external to the conscious self. Scholars no longer defined inspiration as an external source of power, but rather a natural energy of the mind (e.g., enthusiasm and passion) that exists in a person’s own being (Ponsford, 1986).

Contemporary psychologists often invoke the inspiration concept, yet tend to do so informally without defining the term. Therefore, usages vary considerably. Some creativity researchers equate inspiration with creativity. Others use inspiration as a synonym of insight or illumination. Some psychologists continue to portray inspiration as a supernatural phenomenon and hence describe it as unscientific and irrelevant to the science of creativity.

Further complicating matters, some scientists have challenged the importance of inspiration without defining the term clearly. For example, Martindale (2001) endorsed Thomas Edison’s claim that genius is 1% inspiration and 99% perspiration and suggested

that no scientist disputes Edison's claim. What exactly is it that all scientists are purported to believe? That perspiration is important, or that inspiration is unimportant, or both? And what do these terms mean exactly?

It would be imprudent to dismiss the inspiration concept given longstanding interest in the humanities and the nascent state of the scientific literature on the subject. In an effort to investigate inspiration in earnest, Thrash and Elliot (2003) proposed a general conceptualization of inspiration by integrating usages from diverse disciplines. The next section discusses this domain-general conceptualization and subsequent conceptual developments.

Inspiration as a General Construct

Conceptualization

Core Characteristics

The *tripartite conceptualization* identifies three core characteristics that define the state of inspiration: evocation, transcendence, and approach motivation (Thrash and Elliot, 2003). *Evocation* refers to the passive or receptive manner by which inspiration is elicited; one does not feel volitionally responsible for becoming inspired, at least not directly, because inspiration is a response to a stimulating influence. *Transcendence* refers to an epistemic change in which one gains awareness of new and better possibilities. This change often, but not always, occurs during a sudden moment of illumination or insight. *Approach motivation* refers to the motivational impetus to bring one's new vision into fruition. These three core characteristics are necessary and collectively sufficient to distinguish inspiration from other constructs (Thrash et al., 2014). For instance, awe shares with inspiration the qualities of evocation and transcendence but does not involve arousal of approach motivation.

Component Processes

Whereas the tripartite conceptualization identifies the characteristics of inspiration, the more recent component process conceptualization identifies its parts: being inspired *by* and being inspired *to* (Thrash and Elliot, 2004). Being inspired *by* occurs when one is moved by the perceived intrinsic value in an evocative object (e.g., a piece of art, a role model, or a creative idea). Being inspired *to* occurs when one becomes motivated to extend, transmit, or actualize the perceived intrinsic value found in the evocative object. This component process conceptualization is consistent with and complements the tripartite conceptualization. Being inspired *by* gives rise to the characteristics of evocation and transcendence; being inspired *to* corresponds to approach motivation.

Consider some implications of the component process conceptualization. First, evocation and transcendence characterize the same component process and may be viewed as two sides of the same coin. Transcendence requires evocation. Generally, one cannot transcend one's epistemic limits through an act of will; one must be awoken. Second, gaining awareness of better possibilities and ensuing motivation are distinct processes and therefore do not always co-occur. For example, a painter enamored of the grace of mother nature (inspired *by*) may or may not feel compelled to capture the scene on canvas (inspired *to*). Similarly, a spontaneous insight may or may not lead to inspired action. By definition, inspiration is considered present when both the *by* and *to* component processes are activated.

Transmission Model

Most recently, scientists have rounded out the conceptualization of inspiration by theorizing about the function it serves. Inspiration is theorized to motivate the transmission of perceived intrinsic value, such that intrinsic value is transmitted from an elicitor object to an outcome object (Thrash et al., 2010). From a statistical modeling standpoint, inspiration may be viewed as a mediating (intervening) process. Encounter with a source of intrinsic value evokes inspiration, which in turn energizes transmission of the intrinsic value.

Transmission may take any of three forms: replication, actualization, or expression (Thrash et al., 2014). *Replication* occurs when one reproduces the intrinsically valuable features of an existing elicitor object in a new object. *Actualization* occurs when one brings newly imagined possibilities into fruition. *Expression* occurs when ideas flow out swiftly, having arrived well-formed in the same sensorimotor modality in which they are to be expressed. Regardless of which form it takes, inspiration is qualitatively different from most other human motivations. Most are *telic*, or goal focused, whereas inspired transmission is *mimetic*—i.e., imitative, preservative, or expressive (Thrash, in press).

Contrary to the conventional wisdom that inspiration is a purported source or cause of creative ideas, the transmission model clarifies that inspiration is a response to creative ideas; inspiration motivates the process of bringing ideas into fruition. Thrash et al. (2010) have confirmed this empirically. There are two benefits of the proposed model. First, the specified sequence is consistent with scholarship in the humanities, where the concept of inspiration originated. For instance, theologians distinguish inspiration (the human act of articulating divine wisdom) from revelation (God's act of revealing divine wisdom to the human mind). Second, suggesting that inspiration explains the origins of creative ideas would not aid scientific understanding. We are better off ascribing the origins of creativity to the kinds of cognitive, biological, social, and cultural processes that creativity researchers already study. The motivation triggered by creative insight is a topic that creativity researchers have neglected, and inspiration fills this gap perfectly.

Operationalization and Validation

Formally, inspiration is an episode that unfolds across time (Thrash et al., 2014). Such episodes give rise to state and trait variance. At the state level, one may think of inspiration as being more or less present for a particular person at a particular moment. At the trait level, one may think of some people as more prone than others to experiencing episodes and states of inspiration.

General Trait Inspiration

Thrash and Elliot (2003) developed the Inspiration Scale (IS) to assess inspiration at the trait level. The eight-item questionnaire consists of two four-item subscales that assess the frequency and intensity of inspiration. Inspiration frequency and intensity are strongly correlated ($r = 0.60\text{--}0.80$), and therefore a combined score is useful as an overall index of trait inspiration. The IS has excellent psychometric properties. It has the expected two-factor (frequency, intensity) structure, is internally consistent (Cronbach's $\alpha \geq 0.90$), has strong test-retest reliability ($r = 0.77$), and has invariant measurement properties across time and across populations.

Thrash and Elliot (2003) found that trait inspiration relates meaningfully to variables from major theories of personality and motivation. Of the Big 5 personality traits (extraversion, neuroticism, agreeableness, conscientiousness, openness to experience), inspiration correlates positively with openness and extraversion. These traits correspond theoretically with the component processes of being inspired *by* and being inspired *to*, respectively. Regarding motivation correlates, inspiration converges with indicators of approach motivation, intrinsic motivation, and work-mastery motivation. The relation with approach motivation is consistent with the tripartite conceptualization; inspired individuals are motivated to bring new and better ideas into fruition. The relation with intrinsic motivation suggests that inspired activity is inherently enjoyable and fulfilling. Finally, the relation with work-mastery motivation implies compatibility between inspiration and “perspiration.” Inspired individuals are more likely, not less likely, to work hard to achieve task mastery and develop their skills. Other correlates of inspiration include perceived competence, optimism, self-esteem, nostalgia proneness, positive affect, and progress toward personal goals (Milyavskaya et al., 2012; Thrash and Elliot, 2003; Stephan et al., 2015).

General State Inspiration

To validate inspiration at the state level, Thrash and Elliot (2004) compared self-narrated inspiration experiences to narratives of ordinary daily experiences (as a control condition). Inspiration narratives showed evidence of evocation (e.g., passive self, low volitional control), transcendence (e.g., meaning, spirituality), and approach motivation (e.g., activated positive affect; hereafter called positive affect). Thus, the inspiration narratives provided evidence of all three core characteristics of inspiration, supporting the tripartite conceptualization at the state level of analysis. In addition, supporting the component process conceptualization, a confirmatory analysis demonstrated that being inspired *by* and being inspired *to* are distinct and converge meaningfully with indicators of transcendence, evocation, and approach motivation (Thrash and Elliot, 2004).

Inspiration was also found to differ meaningfully from its strongest known correlate, positive affect, a basic dimension of mood that involves feeling excited and alert (Thrash and Elliot, 2004). The two states involve similar levels of approach motivation, but inspiration involves higher levels of transcendence and evocation. Additionally, inspiration and positive affect were found to have different antecedents. Inspiration was predicted proximally by illumination and distally by openness-related traits. In contrast, positive affect was predicted proximally by reward salience (i.e., the opportunity to get something desired) and distally by approach temperament. These findings suggest that inspiration and positive affect serve different functions—transmission and acquisition, respectively.

Inspiration and positive affect have also been found to occur on different days of the week. Whereas positive affect is roughly equally distributed across days of the week, inspiration is more likely to occur on weekdays than weekends (Thrash, 2007). It appears that the TGIF (“thank goodness it’s Friday”) attitude is not conducive to visitation by the muse.

Inspiration in the Creativity Domain

Conceptualization of Inspiration Within the Domain of Creative Activity

Traditionally, as noted, the creativity research literature has not provided a clear definition of inspiration. The solution proposed by Thrash et al. (2010) was to apply the general inspiration construct, based on the interdisciplinary literature review and construct validation research discussed above, to the specific domain of creative activity. From the perspective of the tripartite conceptualization, the general quality of transcendence may be replaced by illumination or insight into a creative solution. From the perspective of the component process conceptualization, inspiration involves being inspired by a creative possibility specifically rather than intrinsic value generally. From the perspective of the transmission model, the function of inspiration may be understood as transmission of a creative idea. That is, inspiration is a response to a creative idea, and it motivates the translation of the creative idea into a creative product.

In light of this model, perhaps it is not surprising that there has been so much confusion about how inspiration relates to creativity. Inspiration is an effect of creativity *in an idea* and a cause of creativity *in a product*. This conceptualization removes any hint of unscientific supernatural influence, while preserving the mimetic spirit of inspired transmission as it has been described for millennia (Clark, 1997).

Because the concept of transmission may seem a bit abstract, the remainder of this section provides examples of the three forms of transmission as they occur in the context of creative activity. The *replication* form of transmission occurs when one perceives intrinsic value in a preexisting object that calls for re-expression in the form of a creative product. The English writer Virginia Woolf described an experience in which an encounter with the world awakened a creative impulse that can be categorized as replication:

Boats float past, through the red, through the green ... Oh I am in love with life ... Now begins to rise in me the familiar rhythm; words that have lain dormant now lift, now toss their crests, and fall and rise and fall and rise again. I am a poet yes. Surely I am a great poet. (Haule and Smith, 1993, p. 51)

Actualization involves bringing a creative insight or feeling into fruition. An example of actualization comes from Romantic poet Percy Bysshe Shelley (1840):

The mind in creation is as a fading coal, which some invisible influence, like an inconstant wind, awakens to transitory brightness; this power arises from within ... could this influence be durable in its original purity and force, it is impossible to predict the greatness of the result; but when composition begins, inspiration is already on the decline; and the most glorious poetry that has been communicated to the world is probably a feeble shadow of the original conceptions of the poet.

Expression involves channeling content that flows out spontaneously in the same sensorimotor modality in which it arises. An example of expression comes from the English poet, Stephen Spender (Chiselin, 1975, p. 118): "My own experience of inspiration is certainly that of a line or a phrase or a word or sometimes something still vague, a dim cloud of an idea which I feel must be condensed into a shower of words."

Further Validation Specific to the Domain of Creative Activity

Having introduced the general inspiration construct to the creativity literature, Thrash et al. (2010) supplemented the original construct validation research with a test of the tripartite conceptualization within the context of creative writing. A questionnaire about the writing process included two items related to evocation (e.g., "these ideas came to me unexpectedly or spontaneously"), transcendence (e.g., "I saw some deep truth when I wrote this"), approach motivation (e.g., "these ideas energized and motivated me"), and overall inspiration (e.g., "I felt inspired while writing this"). Two additional items assessed effort (e.g., "I worked hard in writing this"). A principal components analysis yielded two factors, inspiration and effort. All eight inspiration items converged as indicators of the inspiration factor, and the two effort items converged as indicators of the effort factor. These findings support the tripartite conceptualization and establish discriminant validity (Thrash and Elliot, 2003).

Empirical Evidence of a Relation Between Inspiration and Creativity

A series of studies documented a positive relation between inspiration and creativity (Thrash and Elliot, 2003). In one study, individuals who were more prone to inspiration were found to describe themselves as more creative. In another study, individuals were found to feel more creative on days when they are more inspired. In a third study, US patent holders who experience inspiration more frequently were found to hold more patents. Receipt of patents is an objective and culturally significant indicator of creativity.

Another set of studies focused on inspiration in the writing process. Across three types of writing (scientific writing, poetry, fiction), inspiration while writing was found to predict the creativity of the product, as evaluated by expert coders (Thrash et al., 2010). These findings were robust when a variety of covariates (e.g., effort) were controlled. An and Youn (2018) reported that inspiration predicted a variety of indicators of creativity, including performance on a test of remote associates, as well as originality and fluency on alternate uses tasks. Ngara (2010) documented the importance of inspiration to Shona stone sculptors in Zimbabwe.

Evidence of Transmission

Thrash et al. (2010) conducted a longitudinal study and found that creative ideation tends to precede feelings of inspiration, consistent with the transmission model. In the poetry and fiction writing studies, they also conducted direct tests of the transmission model. In both studies, the creativity of a writer's initial idea (as appraised by the writer) predicted the creativity of the resulting text (as evaluated by expert judges). This effect was mediated by inspiration (as reported by the writer). Other positive affective-motivational states, such as effort, awe, and positive affect, were found not to function as mediators of transmission, suggesting that the transmission function is unique to inspiration.

In the fiction writing study, the researchers also examined how personality influences the transmission process. The trait of openness to aesthetics was found to predict the creativity of the initial idea; approach temperament, in contrast, amplified the effect of

idea creativity on inspiration. Consistent with the component process conceptualization, which posits separate *by* and *to* components, inspiration requires an openness to ideas, as well as a motivational sensitivity to creative ideas as positive incentives. [An and Youn \(2018\)](#) recently reported that inspiration mediates between openness to aesthetics and creativity, as well as between art exposure and creativity.

Other Correlates of Inspiration in the Writing Process

In the poetry writing study, participants who were more inspired reported that their ideas came to them more fully formed. Their ideas were experienced as arising from unconscious or spiritual sources rather than from the conscious mind, and their ideas were experienced as emerging more suddenly and automatically. These quantitative findings are consistent with qualitative autobiographical accounts throughout history.

In their study of fiction writing, [Thrash et al. \(2010\)](#) used screen capture methods to assess objective writing behaviors and related them to the subjective experience of inspiration. Individuals who were more inspired wrote longer texts. This effect was attributable to the fact that inspired writers generated more words, as opposed to deleting fewer words. Inspiration was related to writing efficiency, such that inspired writers retained a greater proportion of the words that they typed. Inspired writers were also more productive in that they generated more retained words relative to how long they worked. Finally, inspired writers spent more of their time inscribing (adding or deleting words) and less of their time pausing. Another noteworthy finding was that writers who were more inspired tended to use shorter words. Together, these findings indicate that inspired writing is highly economical, consistent with the expressive function of inspiration.

Differentiation From Related Constructs

Inspiration is often confused with insight and is often treated as incompatible with “perspiration” or effort. The following sections clarify the relation of inspiration to insight and effort.

Inspiration Versus Insight

Inspiration is sometimes used synonymously with insight to refer to the emergence of creative ideas in consciousness ([Mayer, 1992](#)). Insight is a cognitive event, in which an idea enters awareness. Inspiration, in contrast, is a motivational state that is often triggered by insight. If insight always resulted in inspiration (i.e., motivation to actualize the insight), or if inspiration were always preceded by insight, perhaps there would be little reason to distinguish them. However, insights do not always lead to inspiration. Insight is more likely to lead to inspiration in individuals who have a stronger approach temperament ([Thrash and Elliot, 2004](#); [Thrash et al., 2010](#)). Moreover, inspiration can occur without insight, as when one is inspired by a relatively stable feature of the external environment (e.g., scenery near one’s home or the life of one’s mother). Therefore, insight and inspiration are distinct concepts, and these terms should not be used interchangeably.

Inspiration Versus Perspiration

It is time to retire the practice of pitting inspiration and effort against one another and advocating one over the other. Consider the following arguments.

First, inspiration and effort are positively related and compatible with one another rather than negatively related or mutually exclusive. For instance, individuals more prone to inspiration tend to be higher in work-mastery motivation, and inspiration and work-mastery motivation tend to peak on the same days ([Thrash and Elliot, 2003](#)). Moreover, both lead to higher levels of the other over time ([Thrash and Elliot, 2003](#)). Those individuals who are more inspired to write tend to exert more effort; and, when a given individual is more inspired than usual, he or she tends to exert more effort than usual ([Thrash et al., 2010](#)). Given that inspiration and effort tend to co-occur and reinforce each other, it does not make sense to claim that genius is 99% the latter and 1% the former.

Second, although inspiration and effort are compatible and co-occur to a degree, they are distinguishable constructs that uniquely predict different outcomes. Regarding writing quality, [Thrash et al. \(2010\)](#) found that inspiration predicts qualities that call for transmission or expression (e.g., creativity), whereas effort predicts qualities that call for volitional regulation (e.g., technical merit, use of rhyme). Inspiration and effort also relate to different objective aspects of the writing process. Whereas inspiration is related to the number of words generated, effort is related to the number of words deleted. Similarly, whereas writers who are inspired spend more time inscribing and less time pausing, writers who exert effort spend more time pausing (presumably to think or plan) and less time off task ([Thrash et al., 2014](#)). In short, inspiration and effort play different and complementary roles in the creative process.

Third, inspiration, like effort, is a motivational construct. Therefore, the fact that creativity requires motivation is not a reason to advocate effort over inspiration. In fact, [Thrash et al. \(2010\)](#) found that inspired individuals spent more time writing, whereas individuals who exerted more effort did not spend more time writing. Inspiration and effort both contribute in important ways to making the creative process happen.

Writer-Reader Inspiration Contagion

Plato argued that inspiration is infectious—the muse inspires the poet, the poet inspires the performer, and the performer inspires the audience. Researchers recently conducted the first scientific study of inspiration contagion from writers to readers (Thrash et al., 2017). The core hypothesis was that inspiration may be self-propagating, because the output of inspired transmission in a writer (e.g., an insightful text) may also function as input for inspired transmission in a reader. To test this hypothesis, the poems written in a prior study of inspiration in the writing process were given to a new sample of readers, who were asked to report on their inspiration in response to each poem. Readers also reported their personality traits. A panel of expert judges evaluated poem qualities.

Contagion and Mediation

Analyses indicated that writers who were more inspired wrote texts that were more inspiring to the average reader. This finding provides the first evidence of inspiration contagion. A mediation analysis documented two qualities of the text through which inspiration is passed from writer to reader: insightfulness and pleasantness. Writers who were more inspired generated texts that were more insightful and more pleasant; and insightful and pleasant texts were, in turn, more inspiring. Analyses also revealed one quality of inspired texts that undermined contagion to a degree: originality. Inspired writing was more original, and originality (as distinguished from insightfulness, etc.) tended to undermine reader inspiration.

Moderation by Reader Personality

In this same study, contagion of inspiration was found to be moderated by reader openness to experience. The effect of writer inspiration on reader inspiration was stronger among readers higher in openness. As in prior research, this finding highlights the fact that one needs to be sufficiently receptive to new and better ideas in order to become inspired.

Moderated Mediation

Why are readers higher in openness to experience more prone to inspiration contagion? Perhaps they are more responsive to the insightfulness of inspired writing, or more responsive to its pleasantness, or less uninspired by its originality? Moderated mediation analyses supported this last possibility. Readers high in openness were immune to the undermining of inspiration by originality, whereas readers low in openness were particularly prone to this undermining.

This finding seems to have external validity. Imagine the lineages of creators, innovators, and entrepreneurs who shape our culture. They must be comfortable contemplating new ideas in order to draw inspiration from one another. This finding is also consistent with Plato's suggestion that inspiration contagion occurs among poets, performers, and their audiences, who presumably are high in the trait of openness.

Related Findings

To provide additional evidence of the discriminant validity of inspiration and its covariates, researchers have also examined mechanisms underlying contagion of positive affect and awe (Thrash et al., 2017). Like inspiration, positive affect and awe were found to be infectious, but contagion occurred through somewhat different sets of mediators. Contagion of positive affect was mediated largely by the pleasantness of the text, and contagion of awe was mediated largely by sublimity. Together, these findings provide additional support for the discriminant validity of inspiration and its covariates. Writer effort was a relatively weak predictor of reader states.

Conclusion

Inspiration plays an important role in the creative process, as supported by the following arguments. First, inspiration is a motivational state that directly fuels the creative act. Second, inspiration makes creators more efficient and productive. Third, individuals who are more inspired produce works that are more creative, and a given individual is more creative when inspired. Finally, inspiration has far-reaching consequences. Inspiration is infectious because inspired works embody the spirit with which they were created. It is worth considering whether similar processes occur in other domains, including the contagion of inspiration through scripture and through online media.

Inspiration and effort are compatible and complementary. The opposite of effort is not inspiration; it is laziness. The opposite of inspiration is not effort; it is a lack of inspiration. The ideal is to have a capacity for both inspiration and effort. The former is the fuel that enlivens us as we translate creative ideas into creative solutions. The latter is a volitional resource that helps us power through the less appealing aspects of the creative process.

How are intelligence and creativity related? The question is important because, in our schools, we seem to value intelligence over creativity, but in life, creativity is at least as important because it involves adapting to the novel situations that can lead people either to great success or stunning failure. Not only is the relationship important for theoretical reasons, it also has tremendous applied value in the schools, workforce, and our everyday lives.

The roots of creativity as a scientific discipline are planted in the intelligence literature. Many of the earlier scholars (such as Francis Galton, Lewis Terman, Alfred Binet, and Charles Spearman) who considered and discussed creativity were more primarily focused on intelligence. Indeed, it was an intelligence researcher, [J.P. Guilford \(1950\)](#), who first publicly recognized the need for an independent study of creativity.

[Guilford \(1967\)](#) placed creativity into a larger framework of intelligence in his Structure of Intellect model. He attempted to organize all of human cognition along three dimensions. The first dimension was called ‘operations,’ and simply meant the mental processes needed to complete almost any kind of task, such as cognition. The second dimension, ‘content,’ referred to the general subject matter, such as words. The third dimension, ‘product,’ represented the actual products that might result from different kinds of thinking in different kinds of subject matters, such as writing. With five operations, four contents, and six products, Guilford’s model had 120 different possible mental abilities. Indeed, he later expanded the model to include 180 different abilities, although the 120 abilities model is the one more often studied.

One of Guilford’s operations (or thought processes) was divergent thinking – analyzing one’s response to questions with no obvious, singular answer. Such questions might include “What would happen if we didn’t need sleep?” This work, followed up by other researchers (most notably E. Paul Torrance), has often been used as a measure of creativity. Two of the most common ways of scoring these tests are fluency (the total number of responses given) and originality (how unique are the responses).

Theories of Intelligence Which Encompass Creativity

Guilford placed creativity within the context of an intellectual framework. In doing so, he was the first of many to consider creativity to be part of intelligence. Some theories of intelligence include creativity as a subcomponent. Undoubtedly, the theory of intelligence that is most often applied to IQ tests is the CHC (Cattell–Horn–Carroll) theory, a combination of two earlier theories ([McGrew, 2009](#)). The Cattell–Horn theory initially proposed two types of intelligence, crystallized (Gc) and fluid (Gf). Gc is what a person knows and has learned, whereas Gf is how a person handles a new and different situation (i.e., problem solving). Horn expanded the theory to include more dimensions (known as Broad Abilities). [Carroll’s \(1993\)](#) theory proposed a hierarchy of intellectual abilities. At the top of the hierarchy is general ability; in the middle of the hierarchy are various broad abilities (including learning and memory processes and the effortless production of many ideas). At the bottom of the hierarchy are many narrow, specific abilities such as spelling ability and reasoning speed.

The combined CHC theory incorporates both the concept of a general intelligence (all of the different aspects of intelligence are considered to be related to a common ‘g’, although this aspect is not often emphasized) and the concept of many different aspects of intelligence ([McGrew, 2009](#)). Ten different broad factors of intelligence are proposed. These include Gf and Gc from the initial

[☆] *Change History:* August 2018: RJ Sternberg added abstract and keywords, presentation of triangular theory of creativity, discussion of straight-A model of the creative process, discussion of 5-A model of creativity, additional references/readings. JC Kaufman added discussion of splitting of Gf, discussion of creative metacognition, discussion of problem construction, further comments on threshold theory, additional references/readings. This article is an update of R.J. Sternberg, J.C. Kaufman, Intelligence (as Related to Creativity), Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011.

Cattell–Horn theory. They also include Gq (quantitative knowledge, typically math-related), Grw (reading and writing), Gsm (short-term memory), Gv (visual processing), Ga (auditory processing), Glr (long-term storage and retrieval), Gs (processing speed), and Gt (decision speed/reaction time). Of these 10, only 7 are directly measured by today's intelligence tests: Gq and Grw are in the domain of academic achievement, and, therefore, are measured by achievement tests, and Gt is not measured by any major standardized test. Intelligence tests may indirectly measure some of these other skills, however. For example, intelligence tests indirectly measure achievements in various areas. The Stanford–Binet 5 and the Woodcock–Johnson–Revised were the first intelligence tests to be built on Gf–Gc theory. Today, nearly every major intelligence test is founded either explicitly or implicitly on the current version of the theory, namely, CHC.

Although in the early stages of the Cattell–Horn Gf–Gc theory, Gf (fluid intelligence) was hypothesized to be strongly linked to creativity, such a relationship is no longer explicitly part of the CHC theory. The current model, based on factor analytic studies by Carroll and others, includes originality/creativity as a component of long-term storage and retrieval (Glr). The most recent presentations of CHC theory argue that some Glr narrow abilities impact such creativity-relevant abilities as divergent production, ideational fluency, or associative fluency. In the detailed description of the model, connection is the only mention of creativity, originality, or divergent thinking. Fluid intelligence (Gf) is discussed in terms of its relationship to problem-solving and coping with novel problems (both considered to be highly related to creativity), yet the emphasis is on Glr. There has also recently been discussion of splitting Glr into Gl and Gr, with Gr including the creativity-related abilities mentioned above (Schneider and McGrew, 2019).

Others proposed a differential relationship between Gs (processing speed) and creativity. Creative people are selective with their speed of information processing. Early in the creative problem-solving stage, they widen their breadth of attention, allowing a larger amount of information to be processed (and thereby lowering their speediness). Later, when the problem is better understood, their attention span is shortened and their reaction time is quicker (Vartanian et al., 2007). This theory is reminiscent of Sternberg's distinction between global and local planning: According to Sternberg, brighter people spend more time in initial global planning so that later they do not have to spend as much time in local planning.

Some have argued that the current CHC model short-changes creativity. Placing all references to creativity and originality under Glr (or Gr) seems quite narrow. The ability to draw selectively on past experiences is essential for creating something new. But the connection between fluid intelligence and creativity is minimized in new conceptions of the model. A theory of intelligence that has recently been applied to school admissions is Sternberg's theory of successful intelligence. This theory comprises three 'subtheories': a *componential subtheory*, which relates intelligence to the internal world of the individual; an *experiential subtheory*, which relates intelligence to both the external and the internal worlds of the individual; and a *contextual subtheory*, which relates intelligence to the external world of the individual. The componential subtheory specifies the mental mechanisms responsible for planning, carrying out, and evaluating intelligent behavior. The experiential subtheory expands on this definition by focusing on those important behaviors that involves either adjustment to relative novelty, automatization of information processing, or both. The contextual subtheory defines intelligent behavior as involving purposeful adaptation to, selection of, and shaping of real-world environments relevant to one's life.

The experiential subtheory is directly related to creativity. Sternberg's application assessments of creativity to admissions data increased prediction of college success beyond that obtained with standard admissions tests; in addition, ethnic-group differences were significantly reduced. Gardner's (2011) well-known theory of multiple intelligences does not specifically address creativity. However, his eight intelligences (interpersonal, intrapersonal, spatial, naturalistic, linguistic, logical-mathematical, bodily-kinesthetic, and musical) certainly seem to apply to creativity. Gardner has used case studies of eminent creative individuals to argue that creative people can shine as a function of embodying different intelligences. For example, he selected Freud as an example of intrapersonal intelligence; Einstein to represent logical-mathematical intelligence; Picasso, spatial intelligence; Stravinsky, musical intelligence; T. S. Eliot, linguistic intelligence; Martha Graham, bodily-kinesthetic intelligence; and Gandhi, intrapersonal intelligence (naturalistic intelligence had not been added at this time).

Another theory of intelligence that incorporates creativity is Luria's (1966) neuropsychological model. Like the CHC model, Luria's model is frequently applied to intelligence tests. This model has three functional units; the first unit is responsible for focused and sustained attention. The second functional unit receives and stores information with both simultaneous and successive (or sequential) processing. Simultaneous processing involves integrating chunks of information together, largely in parallel; chunks are synthesized together simultaneously, much as one might appreciate a painting all at once. Successive processing is interpreting chunks of information separately, in sequential fashion, much as when one listens to a news broadcast reporting successive stories.

The third functional unit is responsible for planning, decision-making, and self-monitoring behavior. It is this last ability, planning, that has been hypothesized to be related to creativity. For example, studies have found that planning oriented cognitive styles were strongly linked to creative productivity. Also, people who spent time planning and replanning a project were more productive and more creative.

Theories of Creativity That Encompass Intelligence

Systems Theories

In recent years, there has been an emphasis on creativity theories that incorporate factors that are interrelated. Some of these theories emphasize issues such as the environment or evolution and are less relevant here. Other theories emphasize a confluence of different elements and include intellectual and cognitive abilities in the equation. One such theory is Sternberg and Lubart's (1995) 'investment' theory of creativity, in which the key to being creative is to buy low and sell high in the world of ideas. In

this model, a creative person is like a talented Wall Street investor. A successful creator will generate ideas that may be initially unpopular or underappreciated (as in buying stocks with low price-earnings ratios), yet will persist and convince others of the ideas' merits. The creator will then know when to move on to pursue other ideas (as in selling high, when one divests oneself of stocks).

According to this model, six main elements contribute to creativity: intelligence, knowledge, thinking styles, personality, motivation, and the environment. Intelligence contributes using three elements drawn from Sternberg's triarchic theory (later expanded into the theory of successful intelligence).

The first element is synthetic ability, which is the ability to generate ideas that are novel, high in quality, and high in task appropriateness. Because creativity is viewed as an interaction between a person, a task, and an environment, what is novel, high in quality, or task appropriate may vary from one person, task, or environment to another. Central to this ability is being able to re-define problems. Creative people may take problems that other people see, or they themselves may previously have seen, in one way, and redefine the problems in a different way. This synthetic ability includes three knowledge-acquisition components. The first, selective encoding, involves distinguishing relevant from irrelevant information. Selective combination, the second, involves combining bits of relevant information in novel ways. Finally, selective comparison involves relating new information to old information in a novel way.

The second element, practical ability, is needed to communicate creative ideas to other people (i.e., 'selling' an idea). Good ideas do not always sell themselves – the creative person needs to devise strategies for and expend effort in selling those ideas.

The third component, analytical ability, is often measured by traditional intelligence tests. Yet this component is also related to creativity, as a successful creator must be able to judge the value of his or her own ideas and decide which ones to pursue. Such analytical ability can be used to evaluate the strengths and weaknesses of the idea and determine the best steps to improve upon the idea. People who are high in synthetic ability but low in analytical ability may need someone else to evaluate and judge their work for them. People who are able incisively to evaluate their own work may be said to be high in metacognition (which is related to planning, a key component of Luria's model).

This model has been expanded recently by Sternberg (2018) into a triangular theory of creativity. According to this theory, creativity involves not only defiance of the crowd, but also defiance of oneself and of the Zeitgeist or worldview of one's society. Defiance of oneself means that one is willing to get go of one's prior beliefs and sometimes even creative work to focus on new ideas that may reject or perhaps expand upon one's original ideas. Defiance of the Zeitgeist involves letting go of the presuppositions that have in the past ruled one's creative work.

There has been some empirical work on the role of meta-cognitive abilities in creativity. Some studies have found that people who tended to produce more original responses also were better at rating their most original responses to a divergent-thinking task. In one study, people were asked to pick their best responses to a similar divergent-thinking task, and then examined whether they were more likely to choose responses that outside raters considered creative. Research found that people were able to discern their more creative responses – and that people who were more open to experience were more likely to choose accurately. Further, the concept of creative metacognition has also been proposed (Kaufman and Beghetto, 2013). This ability not entails accurately evaluating one's best creative ideas but also determining appropriate times to share these ideas.

A theory of giftedness that could be argued to be a Systems theory is Renzulli's (1986) Three-Ring Model, which proposes that giftedness is at the intersection among above-average intelligence (measured traditionally), creativity, and task commitment. The circles representing creativity and intelligence overlap. Renzulli distinguishes between two types of giftedness – schoolhouse (i.e., what would be measured by an ability or achievement test) and creative-production. Examples of his components of creativity include Guilford's divergent thinking components (fluency, flexibility, and originality), and being open to new experiences, curious, willing to take risks, and sensitive to aesthetic characteristics.

Another theory that views creativity as a mix of different abilities is Amabile's (1996) componential model of creativity. She argued that three variables were needed for creativity to occur: domain-relevant skills, creativity-relevant skills, and task motivation. Domain-relevant skills include knowledge, technical skills, and specialized talent (i.e., a creative mathematician should know basic algebra and geometry). Creativity-relevant skills are personal factors that are associated with creativity. These skills include tolerance for ambiguity, self-discipline, and risk-taking. Finally, Amabile singles out your motivation toward the task at hand. Intelligence would primarily occur at the domain-relevant skill level.

Cognitive Theories of Creativity

The other group of theories that includes intellectual abilities as a key component is the set of cognitive theories of creativity. Guilford, as discussed earlier, pioneered these ideas, and his convergent versus divergent thinking dichotomy is still a key idea in creativity. Even before Guilford, however, Wallas proposed a model of the cognitive creative process. According to his five-stage model, you first use *preparation* to begin work on a problem. Next, there is *incubation*, in which you may work on other things while your mind thinks about the problem. In *intimation*, you realize you are about to have a breakthrough (this phase is sometimes dropped from the model), and then you actually have the insight in the *illumination* phase. Finally, with *verification*, you actually test, develop, and use your ideas. The Geneptore model (Finke et al., 1992) has two phases, generative and explorative, that are comparable to Guilford's convergent and divergent thinking distinction. In the generative phase, someone constructs a preinventive structure, or a mental representation of a possible creative solution. For example, Elias Howe was working on his invention of the modern sewing machine. He could not quite get the needle correctly designed. Howe had an odd dream in which he was chased by savages who threw spears at him. The spears had a circle loop at the end – and Howe realized that adding the circle (or an 'eye') to the end of

the needle was the solution he needed. The image of a spear with a circle at the end – the image that preceded Howe’s insight – would be an example of one of these preinventive structures. They do not need to be as dramatic or sudden as the realization based on Howe’s dream. Indeed, the generation of preinventive structures is only one part of the creative process, according to the Geneplore model. The thinker must then explore these different preinventive structures within the constraints of the final goal. There may be several cycles before a creative work is produced.

Although the model focuses on the creative process, most tests of the model have actually measured the creative product. In an experiment testing the model, people were shown parts of objects (such as a circle or a cube). They were then asked to combine these parts together to produce a practical object or device. The creativity (and practicality) of the items was then assessed. Interestingly, people produced more creative objects when they were told which parts had to be combined than when they could pick the parts to be combined.

Other theories have also focused on cognitive-oriented components of the creative process. Michael Mumford and his colleagues have argued for an eight-part model, focusing on problem construction, information encoding, category selection, category combination and reorganization, idea generation, idea evaluation, implementation planning, and solution monitoring. Problem construction (also called problem recognition) has been found to particularly predict the overall creativity of a final product (Reiter-Palmon and Robinson, 2009). Mednick (1962) proposed the idea that creativity occurs when different elements are associated together to form new combinations. Creative individuals are assumed to be able to make meaningful, useful associations between disparate concepts and ideas to a greater extent than a relatively uncreative individual. The Remote Associates Test was developed based on this idea.

Robert Sternberg (2017) has proposed a cognitive model of creativity that is applicable to what Kaufman and Beghetto (2009) have called Pro-c (professional) and Big-C (historically significant) creativity. The model describes the sequence of phases people go through and their interaction with the environment when people think and act creatively. The model further specifies aspects of the relationship between creativity and intelligence. The model is referred to as the “straight-A” model of the creative process. It involves five variables—1. activators, 2. abilities, 3. amplifiers, 4. appeal to audience, and 5. assessment by audience. *Activators* are any forces that serve to provoke or to stimulate creativity. The forces can be internal to the person or external—in the environment. There are also deactivators—forces that discourage creativity, such as the time pressure and multiple-choice formats involved with standardized tests. Abilities, of course, include cognitive skills people need to be creative, such as creative, analytical, and practical intelligence. Amplifiers are forces that increase one’s propensity to be creative, such as, according to Sternberg’s triangular theory of creativity (mentioned earlier), willingness to defy oneself, the crowd, and the societal Zeitgeist (worldview). Appeal to audience is the creator’s attempt to fashion his or her work so as to have audience appeal. And assessment by the audience is the audience’s judgment as to whether the work is creative.

In related fashion, Vlad Glăveanu (2013) has proposed a “five A’s framework” for creativity, which includes the actor, action, artifact, the audience, and affordances). The actor (creator) acts creatively, producing an artifact for an audience, within the scope of affordances (opportunities) provided by the environment.

Theories on How Intelligence and Creativity Are Related

The threshold theory argues that intelligence is a necessary but not a sufficient condition of creativity. According to this view, creativity and intelligence are positively correlated up until an IQ of approximately 120; in people with higher IQs, the two constructs are said to show little relationship. The interference hypothesis suggests that very high levels of intelligence may interfere with creativity.

Empirical Work on Intelligence and Creativity

Most studies that investigate creativity and intelligence use divergent-thinking tests (such as the TTCT) or other related paper-and-pencil tests also scored for fluency, originality, or other divergent thinking-related methods of scoring. The studies have generally found that creativity is significantly associated with psychometric measures of intelligence (especially verbally oriented measures, regardless of the type of creativity measured). This relationship is typically not a particularly strong one, although some have argued that the relationship between the latent constructs of creativity and intelligence is underestimated because the analyses only look at observable scores (i.e., performance on an intelligence test). If it were possible to get a ‘true’ measure of the constructs, there might be a higher relationship.

The threshold theory has come under fire. Some have found that the nature of the relationship was dependent on the measures used and the populations tested. Others looked at measures of fluid intelligence and creativity (as measured through divergent thinking tests) and found modest correlations across all levels of intellectual abilities. A longitudinal study of gifted (top 1%) 13-year-olds revealed that differences in SAT scores – even within such an elite group – predicted creative accomplishments 20 years later (Park et al., 2007). A meta-analysis of 21 studies discovered virtually no support for the threshold theory, with small positive correlations found at all levels of ability between measures of intelligence and creativity (Kim, 2005). More recent studies using sophisticated statistical methodology, however, have provided some evidence for the threshold theory (Karwowski et al., 2016).

Nearly all of the studies discussed, however, have a major weakness: the over-reliance on divergent thinking measures as the sole assessment of creativity. Few studies have been conducted that include measures of creative personality, creative products, and

creative processes (other than divergent thinking). Given the distinct characteristics of assessments in these areas, highlighted throughout this book, the threshold theory may be best viewed as largely untested.

Conclusion

Intelligence is strongly valued in schools, and there are extensive and popular measures that are often used. There are usually hundreds of empirical studies about each intelligence test. Creativity may be theoretically desired in school but is often considered less important; some teachers may even dislike creative students. Creativity assessment is murkier than intellectual assessment. The Torrance Tests remain the most used creativity tests despite extensive critiques, although self-reports, teacher ratings, and the Consensual Assessment Technique are also often used.

Few studies contradict the idea that creative people tend to be fairly smart, and that smart people are usually somewhat creative. But some of the tested-and-true ideas about the specific relationship are still unclear. If the threshold theory is correct, then there may be a certain point at which being smart stops helping creativity; recent psychometric studies, however, call the existence of the threshold effect into question.

Both intelligence and creativity are essential component of learning and problem solving in everyday life. Nearly any problem, by the virtue of definition, imposes on its solver some ambiguity that needs to be overcome in order to find the solution. Some theories consider creativity to be subsumed into intelligence and others view intelligence as a core component of creativity. The need of both cognitive constructs in life, however, is undisputed.

Organizations compete in rapidly changing environments. In order to adapt, compete, and serve in these environments, there is a growing need for the generation of new and useful ideas, or creativity, in organizations. Educators, psychologists, social scientists, neuroscientists, organizational scholars, and even occupational therapists study creativity to gather a better understanding about these activities. An intentionality perspective (a perspective that considers purposeful thoughts and actions) adds value to the understanding of how creativity happens and provides new insights about fostering creativity. Considering the “doing it all on purpose” perspective opens the possibility that everyone can be creative, if the skills necessary for creativity are focused on and purposefully learned and practiced. As organizations depend on employees being creative and generating new ideas for processes and products, giving intentionality more attention as it relates to creativity may have deep implications for individuals and organizations as they pursue innovation strategies.

This chapter addresses the notion of intentionality, outlining first what it is closely related to and how it relates to creativity. Then, we provide a number of different ways in which intentionality can aid the creative process at a variety of different levels of analyses. Finally, we highlight how intentionality for creativity can be conceptualized and operationalized as a multi-level construct, residing at the individual, group, and organizational levels of analyses.

Intentionality

When you think about an object, you visualize it in your mind. When you draw an object, your mind guides you to find the correct lines to shape the drawing. When you talk with someone about a topic, your words refer to that topic. Your mind wants to be near and around what you do, how you feel, and how you understand things. In order to address this, Franz Brentano introduced intentionality into philosophy in the last quarter of the 19th century. The *Stanford Encyclopedia of Philosophy* defines intentionality as “the power of minds to be about, to represent, or to stand for, things, properties and states of affairs”. [Malle and Knobe \(2001\)](#) simplify this philosophical definition and use the term intentionality to mean *the purposeful decision to deliberately engage in some action*. Our intentions are expressed with the verbs decide, plan, and intend. When people drive their intentions towards creative activities, they intentionally try to generate creative outcomes.

While creativity scholars have noted the importance of intentionality for creativity, a variety of organizational theories and other fields of studies have long noted the importance of purposeful action by individuals. If we think about developing creativity as developing a competency or skill set, then using a frame of intentionality allows us to gain a number of new insights about fostering creativity in organizations. In order to understand the importance of intentionality and purposeful efforts, goal

setting theory by [Locke and Latham \(1990\)](#) and self-determination theory by [Ryan and Deci \(2000\)](#) are extremely useful perspectives.

Goal Setting Theory

Edwin Locke and Gary Latham propose goal setting theory to describe how developing an intentional plan motivates individuals to reach and be more creative about their goals. Goal setting theory refers to the development of a clear and measurable plan to motivate an individual toward a specific and difficult goal. Locke and Latham argue that both difficulties of a goal and self-efficacy, or confidence about their ability to complete the task, have positive relationships with an individual's performance. Later work of theirs further describes how goals affect performance through different mechanisms. First, goals direct individuals' attention and effort toward goal-relevant activities. Second, bigger goals lead to greater efforts than smaller goals. Third, harder goals extend the duration of the effort than easier goals. Fourth, goals affect performance by leading to arousal, discovery and task-related knowledge and strategies. When people are the most committed to goals, the goal to performance relationship is strongest. Also, individuals' self-efficacy, or confidence about the task, increases their goal commitment. Having summary feedback methods and complexity of task are other effective goal-setting influencers.

Additionally, past performance affects individuals' or groups' future goal choice. Learning goals improve planning and understanding of one's own thought processes toward goal attainment. A person's performance differs whether that person considers a difficult goal as a challenge or a threat. Locke and Latham also argue that goal setting theory can be applied to group and organization levels settings. Since intentionality is a key component of developing a goal-specific plan, being purposeful may be positively correlated with individuals' performance. Intentional plans direct individuals' attention and effort toward goal-relevant activities. Intentional plans improve planning and understanding of one's own thought processes toward goal attainment.

Self Determination Theory

Edward Deci and Richard Ryan propose self-determination theory to describe links between personality, human motivation, and optimal functioning. This theory was shaped by their previous studies about motivation in the 1970s and 1980s. Self-determination theory posits that there are intrinsic and extrinsic motivations and these motivations are strong forces in shaping our behaviors. Ryan and Deci define intrinsic motivation as engaging in something for self-satisfaction. Extrinsic motivation refers to engaging in behaviors for externally generated rewards. This perspective may be adopted to understand how intentionality that is internally generated, versus that which is coached to the individual by an outsider results in different creative outcomes.

The work of Ryan and Deci and self-determination theory has intentionality and purposefulness at its core. Their studies suggest that intrinsic motivation and self-satisfaction are positively correlated with intentionality and purposefulness. This suggests that in order to make purposeful changes in our lives, intrinsic rewards are more effective than extrinsic rewards. In fact, Ryan and Deci argue that self-determination and being in control of one's own life are positively correlated with one's self-motivation, mental health, and well-being, all of which should also set the stage for creativity.

Intentionality for Creativity at Different Levels of Analysis

Individual Intentionality for Creativity

Individuals can make choices to purposefully engage in activities related to creativity on their own volition. That intentionality and purposefulness will enhance one's intrinsic task interest, and thus, should increase that person's creativity. Purposeful and intentional awareness of the present situation becomes valuable to explain a person's creative behavior, creative performance and individual creative outcomes.

Divergent thinking is a connection point to make these predictions between intentionality and creativity. [Runco \(1993, 2007\)](#) states that individuals can increase their creativity by purposefully engaging in divergent thinking during the creative process. Since divergent thinking refers to analyzing many potential solutions in order to generate creative ideas, being purposeful towards doing this would make one end up with more potential creative answers for the problem. As a result, one can then intentionally and purposefully choose the best option among these potential solutions.

As discussed above, intentionality is not a fixed personality trait of a person, but rather a skill that one can develop over time with practice and a better understanding of the notion. It is a helpful tool in early education and development of individuals, but it is not restricted to early education. Educators' intentions and ability to provide a creative environment for students to develop creative solutions contribute to individuals' intentionality. Additionally, educators should also adopt an intentionality perspective to their own behaviors to provide role modeling about individual intentionality. This would help educators better understand their role in developing students' intentionality for individual and group creativity. With

proper techniques, human intentions can be directed toward changes in one's creative performance. Indeed, [Runco \(2007\)](#) states that if people can direct their intentions to enhance their creative performance, they can fulfill their creative potential.

A variety of different bodies of literature have linked intentionality either directly or indirectly to creativity. Specifically, though, which processes can individuals be intentional about engaging in order to stimulate creativity either in themselves or others, and at which levels of analysis do those processes operate? [Shalley and Gilson \(2004\)](#) take a levels of analysis approach in considering factors that relate to creativity at the individual, group and organizational level. They consider the leadership implications for these levels of analysis in terms of stimulating creativity. Their framework serves as an optimal foundation for considering not just leadership as they did, but for considering intentionality and creativity, for it highlights things critical to creativity that can be done with intentionality at all three levels of analysis. Taking an intentionality approach to leading creativity changes the lens and landscape for both our theoretical understand and specific action. An intentionality approach highlights even more the levels of analysis issues for the locus of control and locus of action for creativity. Individuals, leaders, groups and organizations are all entities that can adopt intentionality and influence creativity with specific, focused, and purposeful actions, which we describe next.

Creativity Skills

Individuals need a variety of skills necessary for creativity, including divergent thinking. Some of these skills are problem finding, problem definition or construction, combination, and idea evaluation. Each of these skills in the creative process can be done with intentionality and purposeful search. In fact, creativity is expected to be higher when individuals intentionally focus on the time and processes of these different steps. This additional purposeful search for creative solutions may increase the originality of the solution and result in a more desirable outcome.

Deepening Expertise

[Shalley and Gilson \(2004\)](#) highlight the necessity of expertise and experience that the creativity literature has long posited is critical for creativity. People can become experts in different topics after purposeful practice for a significant amount of time. Groups and organizations can develop core competencies, or become experts in, specific processes and knowledge areas. The focus of this vein of research has been around domain specific knowledge; in order to be creative and craft a unique solution for a specific problem, one must have domain specific knowledge, experience, or expertise in that area. However, more research on the relationship between purposefully deepening expertise should be conducted, as [Jaussi and colleagues \(2017\)](#) found no relationship of purposefully deepening one's expertise at work on the relationship between positive affect and radical and incremental creativity. While their work considers the individual level effects of purposefully deepening expertise and one's creativity, no research to date has further considered this variable or looked at it at other levels of analysis.

External Scanning

External scanning is something the strategy literature has discussed as critical for understand the competitive environment of the organization, and the creativity literature has highlighted its importance for increasing creativity. [Dane \(2010\)](#) discusses the need for experts to reach out into dynamic environments and knowledge areas beyond their domain of expertise in order to circumvent the cognitive entrenchment that can occur with deep domain-specific expertise. Again, without specifically calling it "intentionality", Dane's theorizing implicitly hinges on experts having the intentionality to avoid cognitive entrenchment and purposefully engage in these two primary activities to increase their cognitive flexibility.

Building Creative Self-Efficacy

Creative self-efficacy, or the confidence one has in their ability to be creative, is related to creativity. While things such as supervisor actions, role identity, and transformational leadership have been found to impact one's creative self-efficacy, taking an intentionality lens and applying it to creative self-efficacy moves something potentially considered relatively static in our current research approach (e.g. individuals either have high, medium or low creative self-efficacy and then we consider the implications of that) to a different place of agency. An intentionality perspective would suggest that individuals can be responsible for intentionally knowing their current levels of creative self-efficacy and then engaging in creative tasks to gain confidence and mastery in creativity. Additionally, taking an intentionality approach to creative self-efficacy may suggest that people may intentionally seek out role models in creativity to learn vicariously from them.

One Note of Caution, However, About Intentionality

Some things that individuals do intentionally that work for other types of activities may actually hamper creativity. Measuring and monitoring behaviors related to creativity may be one such example. Long hailed by behavioral modification and goal setting theorists as critical to successful change and goal attainment, measuring and monitoring is often discussed as necessary to keep one's focus on engaging in the behaviors. Yet, measuring and monitoring might have a restricting effect on one's creativity as it will interrupt expression and mental flow, and divert attention from creativity-enhancing processes. In fact, in their research, [Jaussi and colleagues \(2017\)](#) suggest this to be the case. They found that the relationship between positive affect and incremental creativity was significantly weaker when purposeful monitoring was high than when it was low. Erik Dane also reinforces this in his work about mind-wandering. He describes mind-wandering as both an involuntary and voluntary phenomenon, and suggests that not over-focusing, but rather intentionally letting your mind wander, can be beneficial for creativity. Thus, with respect to creativity,

individuals will want to be careful with intentionality about things that may work in other domains as they could significantly negatively impact or inhibit other processes that facilitate creativity.

While individual intentionality regarding certain processes related to creativity can facilitate individual creativity in oneself or others, intentionality can also exist at other levels of analysis as well. Next, we discuss group level intentionality, and consider how intentionality at this higher level of analysis is related to group creativity.

Group Intentionality and Group Creativity

Research on group creativity is growing in volume and in importance, as groups and teams are increasingly popular in organizations. Leadership, group processes, and team composition are important factors for increasing group creativity. Considering intentionality at the group level helps us further understand and theorize more about the kinds of things that may be related to group creativity. Group intentionality identifies the intentionality that happens when two or more members engage in purposeful processes and actions collectively.

As the interactions and exchanges of individuals' unique intentional expressions in a group may result in creative outcomes, groups should intentionally stimulate interactions and exchanges among individual members in order to leverage the benefits of group diversity. To do this, group members may intentionally stimulate collaborations and connectivity in their social networks. Further collaborations in these creative and innovate environments will lead to creative solutions. Group members should intentionally aim to sustain their contribution and use these sustained contributions in the group discussion to generate creative ideas. Brainstorming is one example of a purposeful activity that group members can use to intentionally stimulate these types of social cognitive influence processes. In forming groups, group leaders should intentionally select team members for diversity and design processes to intentionally stimulate interactions amongst the diverse members in the group.

Harvey (2014) theorizes how groups and teams should purposefully create creative synthesis in order to facilitate the highest levels of creativity possible. She further underscores groups needing to engage in intentionality with respect to generating collective attention, or making sure group members are focused on the importance of creativity or creativity goals. She also describes the importance of another intentional behavior of groups, engaging in the enactment of ideas, in order to achieve creative synthesis.

Group Positive Affect

Groups should intentionally create positive group affect, or positive emotions and feelings, in order to facilitate group creativity. Positive affect is both a trait and state variable, meaning that while individuals can possess it naturally, it can also be induced by external factors. A large body of work has pointed to how positive affect can open cognitive channels, or allow individuals to broaden and build their thoughts and associations and form more novel connections amongst ideas (Fredrickson, 2001). Group positive affect can produce these same novel connections amongst group member ideas, thereby contributing to and facilitating group synthesis (Harvey, 2014).

Thus, intentionality for creativity at the group level should focus on purposefully stimulating collaborations and connectivity in social networks, stimulating interactions and exchanges in order to leverage diversity, stimulating cognitive influence processes through brainstorming, and creating group positive affect.

Organizational Design for Organizational Intentionality

The field of organizational design, by definition, holds as a core premise that organizations can and should be purposefully and intentionally designed to create conditions for social and technical interactions and outcomes to occur. Jay Galbraith (1977) proposes organizational design to define the organizational structure and understand the relationship among its components. As noted on Galbraith's website, "Organization design is the deliberate process of configuring structures, processes, reward systems, and people practices to create an effective organization capable of achieving the business strategy."

Organizational design should include up to date technology and information flow in socio-economic systems in order to achieve success in highly competitive environments. People need to understand the technology and information flow to perform more creatively in organizations. Intentional behaviors are helpful to understand the environmental, social, and personal impacts of our daily life decisions. Thus, purposeful commitment to these factors stimulates individuals' learning and creative processes.

An intentional, innovative and interactive environment reshapes intentions and triggers the creative thinking processes of individuals. With this perspective, intentionality and the purpose of creating value may determine how innovative solutions are created. Moolenaar and colleagues (2014) argue that individuals' high intentionality in connecting and interacting with others is positively correlated with their recognition of organizational climate as being more innovative. Therefore, these interactions among peers create a fruitful environment that frequently produces creative ideas. Being purposeful in every part of an action is critical to create a highly connected social network. Therefore, understanding the technology and information flow between and within organizations, and improving collaborations and connectivity of organizational social networks enhance the creativity among individuals and provide innovative and creative environments.

Organizational intentionality for creativity involves purposeful design for systems that foster creativity, such as reward systems, systems that encourage disruption, questioning, and even destruction, and the purposeful inclusion of contextual enablers for creative leadership in their intentional design for creativity.

Reward Systems

Organizations with a creativity and innovation agenda will benefit from intentionally designing systems that reward individuals for their efforts at intentionality around all things related to creativity. Such a design will be a departure for most organizations, who tend to reward around outcomes rather than processes. Adopting an intentionality perspective at the organizational level of analysis suggests that the organization will reward individuals wanting to try, as well as rewarding those who intentionally focus on the more upstream processes for creativity instead of just the outcome. Creativity research scholars have noted the importance of reward systems for creativity. For example, [Amabile \(1998\)](#) describes in great detail how organizations without rewards systems for creativity can “kill” creativity. [Baer and colleagues \(2003\)](#) looked at how reward systems in organizations can facilitate creativity from employees. Interestingly, their research found that rewards boosted creativity in employees who were faced with relatively simple tasks rather than complex ones.

Design for Disruption

Organizations can also be designed in ways that facilitate and celebrate disruption, even going so far as to encourage destruction. As [Runco \(1993\)](#) notes, creativity by definition involves unconventionality and destruction of existing structures and processes. Organizations should have systems in place to encourage questioning, irreverence, and bringing ideas that disrupt or destroy status quo approaches to markets, customers, or operations. Undoubtedly, any organization would benefit from employees bringing disruptive, creative ideas forward.

Contextual Enablers

Additionally, as [Randel and Jaussi \(2019\)](#) note, organizations can also intentionally design organizational level factors that will enable creative leadership. Organizational intentionality focused on enabling the rise of creative leadership will help creative leaders emerge and thrive, which should then further creativity throughout their respective units. Randel and Jaussi highlight how designing for organizational heterogeneity, redesigning processes for the encouragement of entrepreneurial action, and intentionally building the organizational culture to value taking time to fully identify and research problems will facilitate the emergence of creative leadership.

Conclusion

This chapter has described intentionality and its grounding in two closely related constructs, goal-setting theory and self-determination theory. Additionally, it described how intentionality for creativity can increase the likelihood for creativity at the individual, group and organizational levels of analysis. While we know a great deal about how certain phenomena like creative self-efficacy relate to creativity, research and practice would benefit from adopting an intentionality perspective as well, for it allows for the focus to be on purposeful actions that can be taken to increase creativity. As a multi-level phenomenon, occurring at and between the individual, group, and organizational levels of analysis, it opens up a number of fascinating implications and agendas for future research and practice. We hope that our work has been catalytic in inspiring such agendas, and that the creativity world will soon be tasting the sugar and spice of intentionality on creativity. Just as the training literature had to evolve to include training motivation in its theorizing, the time has come to include intentionality in more of our creativity research.

Introduction

Creativity is a complex system which involves not only the creative person and process, but also the creative product and environment. Each of these dimensions contains a variety of components covering different disciplines such as psychology, sociology, arts, history, business, education, etc. In addition, creativity can be manifested at different levels, ranging from eminent, high-level creativity to personal and everyday creativity and in different domains such as discovery in science and geography, design in arts, invention in engineering and technology, reform in politics, changes in society and innovation or entrepreneurship in business, etc. The complex nature of creativity means that creativity cannot be sufficiently explained from only one discipline. Interdisciplinary approaches combine theories and practices of different disciplines and can help obtain a better understanding of creativity. Meanwhile, interdisciplinary communication and collaboration is a creative process, as people of different disciplines need to apply creativity to bridge gaps and create new combinations. Interdisciplinary approaches are often used to foster creativity.

Different Ways of Bringing Disciplines Together

The word “discipline” originates from the Latin words “discipulus” and “disciplina”, which means pupil and teaching respectively. This semantic origin implies that discipline is inherently related to education, whose major activities involve the transmission, transfer, production, and reproduction of knowledge and the development of competences and skills. Scholars have a long history of categorizing different fields of knowledge for learning and teaching purposes. For example, Plato’s academy in 387 BCE focused on Pythagorean number theory, advanced geometry and speculations on science as well as social issues such as education, jurisprudence, politics, and sex. Aristotle’s Lyceum in 335 BCE extended the classification into a wider scope covering different areas which can be further categorized into three classes, including theoretical (knowing and understanding), practical (doing) and productive (making or creating). The appearance of the so-called “scientific disciplines” occurred in the 19th century and since then the division of disciplines has been used by society and educational institutions to classify and organize teaching, learning, and the roles of different professions.

Contemporary universities tend to differentiate two major academic areas - arts and science. The typical artistic disciplines include fine and performing arts, humanities and social sciences. The typical scientific disciplines include natural sciences, mathematics, technology, engineering, and medical fields. It is worth noting that disciplines are not static. The meaning, characteristics and classification of disciplines continuously change when new challenges and demands of society emerge, new discoveries take place or new technologies appear.

There are different ways to bring disciplines together. Scholars advocate a clear distinction among them according to the degree of integration of disciplines. The typical classification is composed of the so-called pluri- or multidisciplinary, interdisciplinarity, and transdisciplinarity (e.g., Klein, 2010).

Pluri- or Multidisciplinary

Pluri- or multidisciplinary combines knowledge and contributions from two or more disciplines without synthesizing or integrating them. In a multidisciplinary team, members work independently rather than interactively. A typical example of such an approach is the writing of this encyclopedia. Hundreds of scholars from a wide range of disciplines come together to present their knowledge and share their opinions about a common topic – in this case, creativity. There is an agreed structure and content paradigm with the editors before compiling the encyclopedia. But once the writing starts, there is no interaction between the authors. Though representing the lowest level of integration, the multidisciplinary plays a valuable role in establishing epistemological foundations for a given subject area, project or program. Therefore, this approach is still widely used.

Interdisciplinarity

Interdisciplinarity takes one step further to not only bring knowledge and contributions of various disciplines together but also synthesize and integrate them through intensive interaction and collaboration. In an interdisciplinary team, members apply different methods, knowledge, and types of thinking of different disciplines to solve questions or complete tasks so that each discipline gains more than it would by working alone. Examples of interdisciplinarity include the development of merging interdisciplinary disciplines such as biochemistry, bioinformatics, neuropsychology, cognitive economics, and organic electronics.

Transdisciplinarity

“Trans” means going across, over or beyond. Transdisciplinarity transcends the boundaries of disciplines through intensive collaboration of disciplinary experts, social practitioners and stakeholders, thus new perspectives, knowledge or systems can be created. The emergence of the transdisciplinarity is closely related to the contemporary epistemological quest for systematic integration of knowledge, synthetic paradigms, problem solving and societal movements for change. Typical examples of transdisciplinarity involve efforts of scientists, politicians, non-scientists, and other stakeholders to cope with complex health problems such as cancer or environmental problems such as climate change.

Transdisciplinary requires the highest level of disciplinary integration of the three. The combination of knowledge from multiple disciplines without synthesis can broaden the horizon but not necessarily foster creativity. The transcendence of disciplines can lead to the creation of new knowledge and systems, but it takes on board not only scientists but also political, social, and economic actors, and even ordinary citizens, thus entails massive investment of time and resources for coordination and management. Not surprisingly, interdisciplinary approaches are more frequently applied in universities and companies to achieve creative and innovative goals. As a result, the focus of the current entry is interdisciplinarity and creativity. Throughout the chapter, interdisciplinary and interdisciplinarity approaches are used interchangeably.

Interdisciplinarity and Creativity Studies

Scholars have agreed that creativity contains at least two defining characteristics: originality and effectiveness (also often labeled as usefulness, fit, or appropriateness). The achievement, expression, and evaluation of the originality and effectiveness involves the participation and interaction of multiple factors in and outside the person. Therefore, creativity can be optimally studied only if multiple components such as motivation, emotion, cognitive abilities, and environment are taken into consideration. Reviews of the status quo of creativity research for the past decades, however, reveal that knowledge about creativity is fragmented and the collaboration among scientists of different disciplines and between scientists and different stakeholders is still limited (e.g., Hennessey and Amabile, 2010). Therefore, calls have been made to make interdisciplinary efforts in studying creativity.

Runco (2007)'s book *Creativity: Theories and Themes: Research, Development, and Practice* was among the first that adopted an interdisciplinary approach. In this book, Runco pointed to the complex and multifaceted nature of creativity and suggested an eclectic approach. He brought together studies from a wide range of fields including behavioral, clinical, cognitive, developmental, educational, organizational, social, economic, historical, and evolutionary perspectives. In the second edition of the book published in 2014, he added two new chapters, including philosophy and creativity, and politics and creativity.

In his second edition of *Explaining Creativity: The Science of Human Innovation*, Sawyer (2012) brought together scientific studies from different disciplines including individual psychology, developmental psychology, cognitive psychology, organizational

psychology, cultural psychology, computer science, neuroscience, biology, arts, and history, etc. As a conclusion, he foresaw the future creativity study to become increasingly interdisciplinary.

In 2017 three important edited books contributing to the interdisciplinary approaches to creativity studies were published. *The Cambridge Handbook of Creativity Across Domains* edited by Kaufman et al. (2017) focused on the complex relationship between domain-general vs. -specificity in creativity. The authors brought together top experts from around the world to discuss creativity across a large number of different domains that cover both traditional domains (e.g., visual art, music, play, dance, engineering, teaching, architecture and psychology) and less traditional domains (e.g., sports, craft, emotions, and photography). One chapter of the book even discussed about animal creativity. What is special about this book is that each chapter discussed the definitions, intriguing research, and potential measures of creativity before making suggestions for development or future directions. This template enabled the exploration and cross-disciplinary comparison of the study and development of creativity in different domains. For example, through the comparison, it is clear that different disciplines give different weight to different criteria in defining creativity: architects emphasize aesthetics in addition to originality, usefulness in photography is defined by the elicited emotional responses in viewers, and in the case of law, institutional constraints and norms are of vital importance. In terms of personality, extraversion appears to be related to creativity particularly to everyday and entrepreneurial creativity, conscientiousness seems relevant to sciences but not arts, and mental illness seems to occur twice as often among writers than non-writers. They anticipate the future as domain transversal and advocate a more pragmatic approach to explore “how and when we can generalize findings and tools from one domain of activity to others or how domain general knowledge or approaches can help us intervene in applied domains” (p. 642).

Acknowledging the need of the dialogue between creativity and innovation, Tang and Werner (2017) summarized their interdisciplinary and intercultural approach to creativity into the *Handbook of the Management of Creativity and Innovation: Theory and Practice*. Their book was inspired by two gaps in the existing bodies of literature: the separation of the creativity and innovation studies and the gap between theories and practice. This book brought together scholars and practitioners from the fields of psychology, education, business, engineering and law to discuss how creativity and innovation are perceived, studied, and managed in different fields and cultures. The authors pointed out that creativity cannot always be transformed into innovation because of the influence of various constraints. They emphasize that “teachers, managers and entrepreneurs need to strike a fine balance between flexibility and control and should adapt the multilevel approach to manage creativity and innovation effectively” (p. 360).

Inspired by the major trends of the contemporary society and the common spirit of openness, collaboration, and innovation, Darbellay et al. (2017) provided a space of dialogue and reflection for scholars and practitioners who are working on design thinking, creativity, inter- and transdisciplinarity, or at the interface of the three areas through their edited book *Creativity, Design Thinking and Interdisciplinarity*. This book brings studies of interdisciplinarity (ID), creativity (C) and design thinking (DT) from the perspectives of psychology, sociology, and epistemology, etc. and explores the complex links between them. The authors of the book reflected on the possible articulations and convergences between C, CD, and ID and highlighted the processes of creative design thinking from an interdisciplinary perspective.

Interdisciplinarity and Creativity in Education

The fast development of modern society has set new requirements on the development of talents. The T-shaped professionals, who have both deep disciplinary knowledge in at least one area and, at the same time, obtain the ability to function and collaborate across a variety of different disciplines and social, cultural, and economic boundaries are in high demand. Interdisciplinary practices can provide a space for teachers and learners to make connections between boundaries, imagine new ways of doing things, explore alternative options, and engage in a personal transformative experience. Below are some typical interdisciplinary approaches that have been successfully applied to foster creativity in education.

Problem-Based Learning (PBL)

Problem-based learning (PBL), also known as inquiry learning, is a student-centered pedagogical approach where students obtain knowledge and skills through the process of solving an open-ended problem. The PBL was first introduced at the Medical School of the McMaster University Canada in 1960s. Since then PBL has been broadened in application not only in medical education but also in almost all fields of learning. The PBL pedagogy draws on the theory of Constructivism, which emphasizes self-directed and collaborative learning in teams. In the PBL process, students work on real-world problems in groups and use the “group intellect” to collect data and information from different areas or domains about the problem. They also take an active part in brainstorming and group discussion to try to bring different subject areas and perspectives together to analyze the problem and propose solutions. There is evidence that PBL is effective in developing higher order thinking such as critical and creative thinking (Masek and Yamin, 2011).

Phenomenon-Based Learning (PhBL/PhenoBL)

Phenomenon-based Learning (PhBL/PhenoBL) is an interdisciplinary constructivist pedagogy where learning is organized in a phenomenon-based, holistic approach instead of a subject-based approach. The learning and pedagogical theories behind the

PhenoBL are actually the same as the PBL. The difference between them is that the PhenoBL is usually used as an umbrella concept which also includes inquiry learning, PBL, project-based learning, etc. In 2016, Finland began implementing a national curriculum reform and mandated that PhenoBL be introduced to the school system alongside the traditional subject-based instruction.

PhenoBL motivates students to learn by studying real-world relevant phenomena. A phenomenon is regarded as anything that can be observed or perceived. In schools, special attention is called to phenomena that are unusual (e.g., natural wonders), interesting (e.g., megatrends) or important (e.g., refugee crisis; integration). It enables the students to break the boundaries of the typical school subjects and develop 21st century skills such as teamwork, communication and critical and creative thinking. The success of such a pedagogical method is obvious: Finland has been best performing country overall in Europe in the Program for International Student Assessment (PISA). And Finland ranks among the top 10 most innovative countries of the world according to the Global Innovation Index.

STEM and STEAM Education

STEM is the acronym of Science, Technology, Engineering and Mathematics. This term is typically used to address educational policy and curriculum choices in schools or universities to improve competitiveness in science and technology development. STEM education is emphasized in many countries because knowledge and skills of these disciplines have strong impact on the development of new technologies, which are crucial for disruptive innovations. However, STEM disciplines are inherently rigid, analytical and logical. The interdisciplinary integration of these disciplines can bring about valuable deliverables, but the potential of coming up with disruptive integrations between these disciplines is limited. As a result, arts has been advocated to be added to STEM in recent years and in 2013 a transdisciplinary, international, open-access journal called "The STEAM Journal" was inaugurated. STEAM relies on breaking down the boundaries between the "hard" sciences and the "creative" arts, thus enabling the students to apply STEM knowledge in imaginative designs in their search for creative approaches to solve real-world problems. STEAM programs add art to STEM curriculum by drawing on design principles and encouraging creative solutions. Inquiry, collaboration (not only in learning but also in teaching), and an emphasis on process-based learning are at the heart of the STEAM approach.

Entrepreneurship Education

In a similar vein, entrepreneurship education brings real-world problems directly from schools, companies or society and relies on interdisciplinary teams to find possible solutions to the problems. Students of various disciplines go through typical design thinking process such as empathizing, defining, ideation, prototyping, and verification to develop concrete processes or products for the problems. Entrepreneurship education seeks to provide students with the knowledge, skills and motivation to encourage entrepreneurial success in a variety of settings.

Entrepreneurship education is carried in three major forms: (1) Regular Entrepreneurship (Start-ups). This is the most popular form of entrepreneurship education. More and more universities worldwide have their own entrepreneurship centers where they work with entrepreneurship consulting companies, companies, start-ups, and incubators, to offer regular courses, selective courses, workshops, summer schools or exchange programs to develop skills and competencies for entrepreneurship. Some programs run a business incubator onsite and operate over a long time period (usually 1–2 years); (2) Corporate entrepreneurship or intrapreneurship. This type of entrepreneurship education takes place at companies that set up a platform where employees can pitch their ideas. Selected ideas then have the chance to be further fostered by being worked through in a cross-functional team, obtaining entrepreneurship training, and other resources. Intrapreneurship is growing quickly: Big companies like Google, Facebook, Microsoft, 3 M, Siemens, and BMW, etc. all have their own intrapreneurship programs; (3) Social Entrepreneurship (Social Venturing). This type of entrepreneurship uses start-up companies and other entrepreneurs to develop, fund and implement solutions to social, cultural, or environmental issues. Social entrepreneurship targets important social problems through cross-disciplinary collaboration with different stakeholders and are either non-profits or they combine for-profit goals with generating a positive "return to society".

Interdisciplinary Research

Interdisciplinary research integrates information, knowledge, data, tools, techniques, concepts, and theories from different disciplines, thus offering the potential of advancing understanding, making new discoveries or solving complex problems. The nature of society and human life is inherently complex. For example, climate change has caused wide concern around the world. But climate change is not only an environmental problem, it is a problem closely related to consumption behaviors (e.g., meat and fast food consumption; plastic packing), globalization and mobility (e.g., ease of traveling by car and plane; flying is cheap and fast), psychology (e.g., selfishness; short-sightedness; inflexibility to give up convenience), business and economic behavior (e.g., aggressive and profit-oriented), and politics (e.g., The Paris Agreement; the recent restriction of diesel cars in Germany). Such complex problems cannot be solved by one discipline alone. Scientists of different disciplines need to work together to advance understanding and search for solutions. To implement their solutions and bring substantial changes, they need more involvement and support from stakeholders at different levels and from the whole society. Meanwhile, the fast development of modern technology provides new ways of learning, living and working, but new technology also poses problems and challenges. For example,

the wide use of Internet and social media has brought tremendous fun and convenience to us, but at the same time, problems of infringement on privacy, obesity, cybercrime, and other problems are challenging the health and safety of people.

As a result, interdisciplinary research has been widely advocated. For example, the US National Science Foundation (NSF) explicitly promotes and supports innovative research projects that require the involvement of several disciplines while exceeding their strict limits to develop new or emerging fields. In the European Union, initiatives such as Citizen Science, Open Science, or Science 2.0 reflect the increasing desire for more demand-driven and participatory research through interdisciplinary collaboration. The Cooperation in Science and Technology (COST) is an initiative to foster bottom-up creativity in research by enabling researchers from academia, industry and the public and private sector to work together in open networks that transcend borders, stimulates knowledge sharing, pools resources, and advance science. The Future and Emerging Technologies (FET) initiative is home for interdisciplinary research, where collaborations between biologists, mathematicians, chemists, psychologists, computer scientists, climate experts, social scientists, neuroscientists, physicists, designers, artists, doctors, engineers, economists and others are participating.

Interdisciplinarity and Team Creativity in Business

Functional Diversity and Team Creativity

Interdisciplinarity in organizational settings is usually understood as diversity in job-related diversity such as functional background or job knowledge-related attributes. There are different types of diversity such as demographic diversity (e.g., age, gender, nationality, etc.) and trait diversity (e.g., personality, cognitive styles, etc.). The focus of the current entry is on functional diversity.

In business and industry, teams composed of members of different functions or expertise are often used to carry out creative tasks and achieve innovative goals, such as product design and production, research and development, or marketing. To date, meta-analyses have slightly supported the positive relationship between functional diversity and team innovation. In one meta-analysis of 104 independent studies, a small effect size (average $r = 0.16$) was found between job-related diversity and team creativity (Hülsheger et al., 2009). The small effect of the interdisciplinarity on creativity in business could be due to the double-edged effect of diversity on creativity. The positive side is that people from different functional backgrounds bring different knowledge, expertise, skills and perspectives together and this could increase the chance of coming up with new ideas or solving complex challenging problems that cannot be solved by one discipline alone. The negative side is reflected by the fact that “Birds of a feather flock together.” Similarity breeds attraction. People have a natural tendency to communicate and interact with people who have similar attitudes, values and beliefs. Meanwhile, due to lack of understanding and different mindsets, people of different disciplines tend to think their own disciplines better than the others. This social categorization process will often lower the quality of communication and collaboration, decrease team cohesiveness and heighten relational conflict, which are all detrimental to team creativity. Hence, it is recommended that researchers look deeper into the team process (e.g., vision, external communication, support for innovation, task orientation, and internal communication; Hülsheger et al., 2009) and examine how the relationship between team diversity and team performance (including creativity) are mediated or moderated by variables related to task characteristics, team climate, leadership styles, managerial support, and organizational culture, etc (van Knippenberg, 2017).

Factors Between the Functional Diversity-Creativity Link

Interdisciplinary efforts involve not only the management of knowledge but also the management of the creative process. Many person-, system-, or environment-related factors influence the link between the functional diversity and creativity in business. Through a systematic review of the existing studies, Knippenberg (2017) revealed that functional diversity can be translated into creativity through the intermediate facilitating effect of the effective exchange of information among team members, their boundary spanning abilities and their communication with external members. He also found some factors influence the strength or direction of the link between functional diversity and creativity. For example, functional diversity is more likely to lead to creativity under one of the following conditions: (1) when the manager has a participative (i.e., shares the decision-making abilities and practices social equality) or transformational leadership style (i.e., serves as a role model, inspires and motivates followers, helps followers with self-actualization, challenges followers to be creative); (2) when the team climate is more supportive of innovation; (3) when the team is more open-minded; (4) when the team members are able to take perspectives of others. The influence of other factors in the complex relationship between interdisciplinary and creativity need to be tactfully managed to get creative outcomes from diversity.

Challenges and Recommendations

As mentioned, diversity (including interdisciplinary or functional diversity) has a double-edged effect. To leverage the positive potential of disciplinarily (or functionally) diverse teams, we need to manage the paradoxical effect tactfully. This section will summarize typical challenges of applying interdisciplinary approaches to creativity and make recommendations on how to meet these challenges.

How to Communicate in Interdisciplinary Teams?

The fact that different disciplines have different jargons and use different methods approaching problems may cause stress, biases, stereotypical thinking or misunderstanding in communication. Therefore, an important step in the interdisciplinary approach involves overcoming of differences in jargon and methodologies and the development of a common language. The following approaches can be helpful to promote the communication in interdisciplinary teams: (1) Each discipline should take time to learn basic jargons and terms of other disciplines; (2) Each discipline should learn to appreciate the value of differences; (3) Project managers can create an easily understandable cognitive diagram to guide the cognitive communication of the team; (4) Communication should occur frequently at different levels to make sure that problems are communicated and addressed in a timely manner; (5) Both internal and external communication should be utilized to obtain necessary support and resources to translate interdisciplinarity into team creativity.

How to Deal With Conflicts in Interdisciplinary Teams?

Conflicts break harmony and cause stress and tension, therefore, many people try to avoid conflicts. However, this attitude is irrational. Creativity studies differentiate two major types of conflict: Task (or cognitive) conflict vs. relationship (interpersonal) conflict. Task conflict is caused by differences in opinions or perspectives which are typical for interdisciplinary teams. Relationship conflict often results from personality differences, between individuals. A recent literature review of over 30 relevant studies provides evidence that task conflict has a positive effect on innovation whereas relationship conflict has no effect or a negative effect on innovation (Vollmer, 2015). Therefore, it is advisable that interdisciplinary teams should (1) be aware that harmony and comfort in a team can kill creativity as this might be the beginning that teams stops creating new things; (2) learn to differentiate different types of conflict and get ready to embrace constructive task conflict, which is conducive to creativity; (3) formalize the communication processes to make the conflict management a proactive tool for managers; (4) establish a supportive cohesive team environment so that interdisciplinary teams can effectively use conflict to improve creativity and innovation.

How to Integrate Different Disciplines?

Well-designed programs which provide effective interdisciplinary communication and collaboration can lead to creative solutions to problems. Luckie et al. (2013) compared three types of interdisciplinary experiences of students from chemistry, biology, and history of science courses: the low-dose model, where students heard cross-disciplinary references from the other disciplines and experienced periodic interdisciplinary exercises; the medium-dose model, where students of different disciplines work collaboratively in their labs; or the high-dose model, where students and faculty members in all three courses met on a weekly basis for discussions to draw connections across the disciplines. They found that the high-dose model had the greatest impact in transforming students' views and achieving creative results. This study suggested that the effective interdisciplinary learning requires sustained effort and frequent communication over time with recurring opportunities for students to identify and explore topics that bridge the disciplines. Critical reflection and metacognition are essential to interdisciplinary learning. Digital tools such as e-portfolios, e-mindmaps, online archives, design labs, and makerspaces are frequently used to facilitate the reflections of interdisciplinary teams and facilitate the interdisciplinary collaboration.

How to Evaluate the Success of Interdisciplinary Efforts?

One recent study of 900 research-center-based scientists and their 32,000 published articles concluded that interdisciplinary research is a high-risk high-reward endeavor: high-risk because interdisciplinary research suffered from a low productivity in acceptance for publication; high-reward as measured by increased citations once published (Leahey et al., 2017). The authors, therefore, suggested that the scientific community needs to consider different ways to evaluate scholarship for scientists engaged in interdisciplinary research.

In functionally diverse teams in business, the time and resources needed to construct, coordinate and manage teams can be at the cost of the productivity of the teams. As in educational settings, the adaptation of an assessment system for interdisciplinary projects can be an effective way to balance productivity and creativity. The complex nature of interdisciplinarity and creativity implies that the traditionally quantity-based summative evaluation is not suitable for assessing interdisciplinary efforts. Rather, formative evaluation of the process of team building, communication, collaboration, conflict management, idea generation, the originality and potential usefulness of the collaborative outcomes and idea implementation should also be measured to improve individual and team development. Flexibility in the evaluation of the outcomes of interdisciplinary collaborative projects is needed because new unplanned outcomes might occur.

How to Lead Interdisciplinary Teams to Achieve Creative Goals?

Interdisciplinary efforts involve not only the management of knowledge but also the management of the creative process. Therefore, the importance of creative leadership cannot be underestimated. As mentioned in the previous section, leadership styles, particularly the participative and transformational leadership styles are important mediating factors which enable the translation of functional diversity into creativity. A recent study found that these two leadership styles, particularly transformational leadership, are indeed important predictors of creativity (Mainemelis et al., 2015). In contrast to transactional leaders, who focus on supervision, control, organization and performance, transformational leaders emphasize inspiring, empowering, and stimulating followers to exceed normal levels of performance. Whereas transactional leaders lead through rewards and punishments, transformational leaders lead through personal-coaching/mentoring and allow followers to have freedom of choice (Bass, 1998). Participative

leadership, also known as democratic leadership style, describes the leaders who involves all team members in goal setting, problem solving, strategy development and task implementation. Participative leadership has a strong positive effect on innovation, as team members feel respected and empowered, thus more motivated.

In addition to the above-mentioned creative styles, Mainemelis et al. (2015) summarized the creative leadership into three major purposes: facilitating, directing and integrating (heterogeneous creative contributions). They stressed that a successful creativity leader of diverse teams should also embrace and balance competing demands on creative leaders such as novelty vs. usefulness, idea generation vs. implementation, cooperation vs. competition, and exploration vs. exploitation.

Conclusion

Interdisciplinary approaches have been widely used in creativity studies, education and organizations to help understand complex phenomena and foster creativity. However, the implementation of such approaches poses challenges for communication, conflict management, evaluation, leadership and management. Therefore, more studies should be carried out to examine the relationship between interdisciplinarity and creativity, and more practices are needed to help improve the management of diversity, creativity, and innovation.

Introduction

Interior design, by nature, involves the act of creation. Creative interior design makes our lives comfortable, enjoyable, rich, safe, healthy, efficient, and organized. It inspires us, transforms our lifestyles, and helps us realize the beauty of surrounding space and every day artifacts. An interior space astutely choreographed can positively influence people’s day-to-day behavior, micro- and macroscale social interactions, multidimensional perception and emotion, and eventually physical and psychological well-being.

Creativity is a critical attribute for interior designers, and nurturing creative problem-solving skills is one of the significant goals of higher education (Runco, 2004); however, design is a complex and somewhat mysterious activity encompassing “many intangible elements, such as intuition, imagination, and creativity” (Zeisel, 2006, 19). Thus, understanding the creative design process is hardly easy and only partially possible from inference through the observation of the behavior of designers, produced artifacts like sketches and drawings, interview, and analysis of designer’s verbal protocols.

The rich relationship between interior design and creativity has been somewhat fragmentally discussed thus far. From the perspective of creativity as a multifaceted phenomenon, we address interior design creativity in terms of product (qualities of creative interior design), process (strategies for creative outcome), and person (prerequisites for creative interior designers). Instead of dealing with creativity in general, we discuss the special link between interior design and creativity by proposing a synthesized framework for a domain-specific understanding of creativity in interior design.

What Is Interior Design?

Interior design is a profession that calls for creativity to shape spaces that meet human needs and enrich people’s lives. Interior designers plan, design, create, invent, and construct spaces where people can live, work, study, play, and engage in various activities. The range, realm, and work scope of interior design are diverse in terms of countries or regions where the task takes place. In countries with rigid requirements for professional qualification, a relatively clearer work scope of interior design is observable; but in other contexts, the scope is somewhat loosely defined.

The confusion in defining the scope and roles of interior design is attributed to diverse nomenclature, such as interior decorator, interior designer, and interior architect (Whitehead, 2017). As one might imagine, the scope of the work of the interior decorator

concentrates on the ornamentation of rooms with artwork, accessories, fixtures and lighting; for an interior designer, the scope involves selecting finishes and fixtures for existing spaces, space planning, and renovation of existing space; and for an interior architect, the scope entails the allocation of new spaces with stronger interdependence of architecture, considering the site and other architectural elements.

The International Federation of Interior Architects/Designers (IFIs), the sole international federating body, has described the responsibilities of interior architects/designers as follows:

- (a) identify, research and creatively solve problems pertaining to the function and quality of the interior environment;
- (b) perform services relating to interior spaces including programming, design analysis, space planning, aesthetics and inspection of work on site, using specialized knowledge of interior construction, building systems and components, building regulations, equipment, materials and furnishings;
- (c) prepare schematics, drawings and documents relating to the design of interior space in order to enhance the quality of life and protect the health, safety, welfare and environment of the public. (IFI, n.d.)

The descriptions above deliver the essential aspects of interior design; it is multifaceted because design activity requires understanding complex aspects of human needs—physical, mental, and emotional. It requires knowledge in diverse areas—design, construction, and systems (e.g., building systems, materials, finishes, and furnishings) as well as standards and regulations. The scope has changed from more decorative aspects in the past to a more holistic approach, including programming and space analysis and planning. On the practice side, interior designers traditionally handled the enhancement, embellishment, and decoration of space; and architects handled allocation of spaces, involving structural and mechanical aspects; but in the 21st century the work scope of interior design has become more collaborative.

In the following sections, we will discuss how interior space is shaped, the qualities of creative interior spaces, strategies for the creative design process, and prerequisites of creative interior designers.

Shaping Interior Spaces

The main goal of designing an interior environment is to support intended activities and to enrich human experiences. Behavioral neuroscientists believe that environment plays an important role in human behavior. The holistic composition of spatial configuration, the vigilant curation of the interlacing of the paths of people's movement, interrelationships among thresholds to rooms, and the orchestration of furniture and other interior components can elegantly foster social interaction among end users. The strategically handled adjacencies among the spatial programs in a workplace environment can promote workplace creativity. In fact, the physical work environment is known to indirectly impact workplace creativity by contributing two significant sociopsychological conditions: dynamism and freedom (Vithayathawornwong et al., 2003). Artistically applied visual components in a themed restaurant captivate the guests. A low ceiling can be strategically put before an open airy space to accentuate the feeling of release after a person progresses through the compressed space. A unique way of treating patterns, surface materials, colors, furnishings, and decorative elements can create deeper meaning and appealing expression.

The way humans shape the interior environment has evolved along with the development and advancement of human history, as shown in the ways humans have responded to social, economic, cultural, and technological transformation. Human aspiration for aesthetics has changed, reflecting such transformation; and the ways to achieve an aesthetic level have also evolved according to changing expectations. Once the first successful design becomes an exemplar for other designers, who follow the key innovative aspects of the design principles, a unique attribute becomes a leading trend. After a while each of these trends becomes a standard form, losing its momentous significance, excitement, mystery, and surprise that such design once displayed. It becomes an ordinary space, and people seek more inventive approaches fresh to the eyes.

In art history, Kubler (1962) defined the first inventive leading example as the “prime object”: This idea applies to interior design practice as well. Prime interior space design is often featured in design magazines and valued by many designers and the general public because of the unique way of solving problems and achieving aesthetic goals. As time passes, many designers may take the same or similar approach; but the key aspects used for the prime interior space design undergo an evolutionary process, producing new developed forms or experiencing rebirth and combination with other contemporary features or becoming forgotten and remembered only in history.

“Creative” Interior Design: Product and Artifact

What attributes define creative interior design? Researchers of creativity typically characterize creative design as both original and useful. Because each profession has its own perspective on creativity, a defined domain-specific set of criteria for evaluation and judgment of creativity is necessary. In a broader sense, in terms of the applicability of the general characteristics of creativity to the field of interior design, appropriate solutions are sought to meet various spatial needs with imagination and exploration to satisfy the client's aesthetic expectations. Because of the high level of complexity that interior design entails, however, various aspects must be discussed in a more comprehensive way in order to explain the unique attributes of domain-specific creativity in interior design.

Unconventional Approach to Problem-Solving

Interior designers engage in acts of solving diverse space-related problems based on an understanding of the varying needs of a client and users. Many researchers have argued that creative activity is, in one way or another, a form of problem solving. Creative problem solving involves a unique approach to meeting all the functional requirements in an exclusive as opposed to a conventional way. For instance, after a few years a restaurant owner may realize that he has lost customers because his restaurant space does not really express its own identity and the space is generally too noisy. Numerous solutions could be used to address these two problems. Simple solutions, such as adding typical acoustic tiles on the surface of the existing ceiling and changing the name of the restaurant, would not be perceived as creative solutions. Instead, a more creative approach may entail redesigning the ceiling with fire-rated sound-absorbing material with color and shape specifically designed to express the distinct characteristics and identity of the restaurant as well as to absorb sound effectively. A design solution that is unique and simultaneously fulfills both the functional requirement and aesthetic expectations is considered a creative design: e.g., interior Designer Eva Maddox transformed the atrium space in George and Helen Smith Athletics Museum into a five-story high spatial museum by incorporating graphic murals, digital displays, and suspended glass vitrines for trophies. Viewers are able to immerse themselves in the three-dimensional exhibit and experience the feeling of becoming part of the story (see Fig. 1).

As new challenges arise in an increasingly complex world, interior designers must deal with numerous problems at once. Unknown future problems may arise as a result of the transformation of dynamic social relationships among users, the reshaping of individuals' lifestyles, the evolution of materials and technology, and modifications in environmental needs. Regardless of the types of challenges, aspects of creative problem solving are likely to fall into the following categories from the macro to microlevel: (a) thoughtful spatial allocation: organization of zones, spaces, or rooms (e.g., a creative arrangement of rooms that encourages social interaction); (b) careful treatment of space-defining elements (e.g., perforated screen partitions in a restaurant defining each space without losing visual connectivity); (c) attentive planning of the circulation pattern (e.g., a carefully designed circulation path to foster informal encounters and unexpected innovation among employees); (d) strategic use of furniture and configuration of interior elements (e.g., a uniquely shaped reception desk that could also accommodate an ADA counter); (e) innovative use of materials, resources, and technology (e.g., the use of smart glass for a conference room to control visual privacy); and (f) artful use of texture, color, and light (e.g., the use of a certain color and texture for particular psychological comfort and well-being). These are not ontological categories but can be used as lenses through which to view aspects of creative interior design in various contexts.

Enriched Aesthetic Experience

Creative interior designers achieve novel aesthetics suited to a specific space by considering the project type, cultural and social context, and needs of the client. The style of aesthetics can be diverse according to the purpose of the space and the designer's intention. For example, appropriate aesthetics differ per bar, sports center, hospital patient room, and spa. For a popular pub near a college town, exciting and invigorating aesthetics may work well, but for a spa at an assisted living complex, more calming and relaxing aesthetics will likely work better.

Figure 1 George and Helen Smith Athletics Museum designed by Eva Maddox. Photo credit: Joori Suh.

The definition of *aesthetics* has two parts: “(a) a set of principles concerned with the nature and appreciation of beauty; and (b) the branch of philosophy which deals with questions of beauty and artistic taste” (Aesthetics, 2019). The first definition relates to the psychological aspects of aesthetics—the principle of aesthetics that results in emotionally pleasing responses. The second denotes aesthetics as a discipline. Observing design studio conversation between instructor and students, Cho (2011) found that discussions of aesthetics occupied two primary realms: the visual and the spatial. That is, the majority of discussions on the aesthetics of interior design involve the visual aspects of a space, including color, finishes, and shape of the space; or elaboration on the spatial experience, including spatial quality, organization, or sequence of spaces. Aesthetics in creative interior design reflects the essential quality of the space and involves more bodily and sensory experience appealing to sight, sound, smell, touch, and taste. According to Whitehead (2017) atmosphere is the pervading tone or mood of a place and the “sense that the interior can convey an impression of its inhabitants” (p. 16). Juhani Pallasmaa (1996) criticized the tendency in modern architecture to be overly oriented to the sense of sight, arguing for more inclusion of other sensory experience. Altogether the finishes, sounds, and aromas contribute to the creation of a unique atmosphere that one cannot imagine in other places, resulting in symbolic aesthetics for the individual. For example, architect Peter Zumthor designed a spa in Switzerland called Therme Vals, renowned for capturing a magical mood with rich sensory and poetic experience.

The aesthetic experience is the result of the interaction between the atmosphere of the physical space itself and the emotional experience of people. Thus, the familiarity and expertise of people resulting from education, prior experience, and cultural or other aspects of individual backgrounds will impact the aesthetic experience. In addition, the perception of aesthetics held by designers and laypersons could differ. Thus, in the creation of interior space, designers anticipate considering laypersons’ perspectives and advocate aesthetics for the public.

Symbolic Meaning and Value

Typically, interior design demands (a) an organizational concept to meet programmatic requirements and (b) a character concept to satisfy thematic or stylistic needs (Rengel, 2014). The character concept of the design often becomes a metaphor that arouses associated meaning and emotion. Creating such metaphors in interior space plays an important role in making the space unique, memorable, and experientially engaging for the users. In her design narrative framework Ganoe (1999) included innovation as one of the criteria that define the significance of design meaning and purpose. Innovation here involves the quality of design that expresses and creates an original meaning. Many creative interior designs exude power, which is usually the result of the additional meticulous and artful expression of significant meaning or the philosophy of a designer. The expression could be applied to the fine detail of the interior elements, materials, colors, forms, or calligraphy to convey a certain impression as a powerful message. Meaning making is evident in the history of interior design as a form of iconographic images or symbols added to significant spaces.

Introduced by Swiss theoretician Ferdinand de Saussure (1875–1913), semiotics applies to interior design in that the particular design concept as *signifié* (signified) is expressed through *signifiant* (signifier), a total image created by interior design elements. Many creative contemporary interior design examples could be explained based on their imbedded symbolic meaning. For example, at the IBM Watson Center, the CNC-milled aluminum plate wall pattern was designed to reflect big data pertaining to the mobile sales of the company as a spatial narrative. Functionally, the perforation in the metal partition works as a layer to emit light behind the perforated plate. Instead of using a simple lattice pattern, the design firm Synthesis Design + Architecture intentionally used a data-driven method so that people can relate the decorative pattern with the implied meaning.

Another example is Kia Beat 360, a multipurpose brand experience center located in Seoul, Korea (See Figure 2). Constructed with a series of connected modular elements, the parametrically fabricated structure functions as a divider between spaces, and its dynamic three-dimensional patterns allow the structure to elegantly and symbolically deliver the brand philosophy: “a different beat” (Kia Beat 360, 2018). French designer Phillipe Starck often uses metaphorical elements to arouse wonder and imagination.

Figure 2 KIA Beat 360 designed by Ca Plan. Photo credit: Ca Plan Co.

The metaphorical materials that he uses are common and almost trivial, such as pool tubes, lighting, and mirrors; however, the extraordinary way he integrates these materials into his interior design raises powerful emotions in viewers. As he explained, these elements are used to introduce “fertile surprises” into the “mental game” he creates (Stark, 2013).

Inventive and Explorative Attribute

Humans have strived to make space more convenient and comfortable to accommodate various activities in interior space. Interior designers have solved complex problems by employing available resources. We see the quality of creativity when a particular interior design displays an inventive approach to solving problems by actively devising unconventional ways of using known materials or resources; by integrating new materials using new technology; or by bringing new insights into the known making process.

Humans have searched for mystery and curiosity in their lives, and this desire has pushed interior designers to surpass conventional wisdom and seek something new. Creative exploration using the computational making process, such as parametric design and 3D scanning and printing, revolutionized the way designers approach spatial design and create interior design components. Unconventional ideas and design can be generated by the computational generative process, fostering the production of unexpected and extraordinary forms. This inventive approach typically involves the creative fabrication process and integration of inventive assembly methods instead of simple application of materials, colors, and finishes. The inventive quality can also be achieved by integrating new insights into existing technology or construction techniques. Warren Platner’s creative use of fan vaulting-inspired ceiling design at the American Restaurant in Crown Center, Kansas City, was an exemplar (see Fig. 3). Platner used the vaulted ceilings in Gothic architecture as his inspiration and exercised his modern interpretation of a historic element to manipulate it with a modern flair.

The four qualities of creative interior design introduced above are not mutually exclusive; instead, they contribute holistically to making the interior space creative.

“Creative” Interior Design Process

The process of interior design is typically defined as follows: (a) problem definition (i.e., through research and analysis of clients, sites, and context), (b) concept development (i.e., through analysis and precedent studies); (c) schematic design; and (d) design development. In practice, it advances further to construction documentation, implementation of space, and Post Occupancy Evaluation (POE).

Many creativity researchers have strived to identify effective ways to engender creative ideas. Unlike fine art, which ultimately pursues the embodiment of the artist’s imagination, interior design begins with a clear understanding of the problems and issues; the cultural, social, and geographical context; and the client. Appropriate knowledge of human, space, and a clear contextual understanding precede creative interior design. Thus, the creative interior design process begins with the research phase, during which an interior designer gathers information about the basic guidelines of the project type, significant contextual data that might influence

Figure 3 American Restaurant in Crown Center designed by Warren Platner. Photo credit: McGraw-Hill Education.

the design, social dynamics among individual users, sociocultural specifics of the client and the future users of the space, and a precedent study of current practice. In order to link the information gathered in this phase with creative ideation, the designer should be cautious and use the information as resources but not for direct inspiration.

Generative Approach to Ideation

The design process entails a “constant iteration of analysis, synthesis and evaluation processes between the two notional design ‘spaces’—problem space and solution space” (Dorst and Cross, 2001, p. 434). By expanding the solution space, which is the number of potential answers to the problem, designers are not limited to an ordinary formula. The creative iteration process that leads to expanded solution space can be initiated from the precedent study, the goal of which is to understand the convention in order to explore more advanced or new ways of solving similar problems; however, in image-based precedent study, if not conducted properly, often causes design fixation (Jansson and Smith, 1991). The critical point is to understand the design as a collective whole: When collecting precedent examples, organizing them under certain categories or archetypes, a designer can recognize the (a) core principle that was applied to many cases and (b) parameters that distinguish each case from the others (Suh, 2017).

For instance, a designer who finds a series of interior design examples with a thick wall with several alcoves may name such a phenomenon “wall nook” and define this archetype as “an alcove space created inside a thick wall” as a core principle. The designer may also recognize that the nook can be shaped variously (deep, shallow, round, rectangular, bottom of the wall, high up in the wall, etc.) to support various activities (sleep, study, gather, eat, or relax). These variations become parameters. Cornell’s intypes (interior archetypes), established by Jennings (2007), are useful for understanding contemporary practices in interior design and the generative potentials imbedded in each archetype. Understanding design based on this core principle + parameter structure encourages the designer to take an active generative approach in the ideation process, thereby expanding solution space.

Once the precedent study and information gathering phase have been sufficiently performed, the designer takes the step toward ideation. Without the appropriate process of ideation, in most cases the proposed design becomes another conventional variation of the precedent example, falling short of innovation. Scholars have introduced design heuristics to facilitate designers’ creativity in the ideation process. Derived from Greek *heuriskein* (meaning to find out, to discover), a heuristic method is a technique used to aid problem-solving and the discovery process by incorporating various exploratory strategies. Yilmaz et al. (2016) suggested design heuristics to revamp fixed ideas by using 77 different methods to alter, modify, adjust, or reshape the initial idea: e.g., change direction of access; change geometry; layer; and repeat. Once modified for suitability to the domain, such design heuristics can be applied to interior design to foster expanding the solution space. Von Oech’s (1992) Creative Whack Pack consists of 64 creative thinking strategies that push the designer to think outside the box: e.g., drop an assumption, make a metaphor, look to nature, and simplify. Some of them encourage the designer to change attitude toward the design process, and others suggest breaking the conventional way of thinking and inspire the designer to try other strategies.

Combinational Method

Many researchers emphasize the importance of a certain structured process of ideation. Among these, the benefit of the combinational method of ideation is often discussed to discover what to combine and how to combine in order to enhance the creative generation process. The combinational method values what the whole can create by combining more than two known concepts, ideas, or design components. In interior design, the combinational process can be employed at the early conceptual level of ideation and also during the design process.

The basic combinational ideation structure suggests that a designer first initiates various primary ideas to create a pool of sources and then generate more complex new ideas by combining two or more primary ideas from the pool (Suh and Cho, 2018). The combinational process can be applied to the (a) form-making process by combining two-dimensional and three-dimensional design components from one scheme or from several schemes and (b) problem solving-focused practice by integrating multiple solution concepts, perspectives from various disciplines, a variety of theoretical approaches, or new technology. For instance, a stairitorium is a grandiose stair space where people can walk up and down as well as sit, relax, study, and gather as a small or large group for various activities. By combining the functions of vertical transition and casual gathering, a stairitorium serves a variety of activities and maximizes the real estate value of the space.

Collaboration

The practice of interior design requires collaboration among peer interior designers as well as other relevant stakeholders, including architects, lighting designer, furniture designer, structural engineers, digital fabrication experts, builders, material specialists, and clients. The design discipline has been traditionally considered one in which sole authorship “by a creative individual in isolation [instead of] a group of individuals” is valued (Constantino and Cho, 2015), so designers often hesitate to collaborate because of the assumption that the authorship of the design is lost and they may be unable to use their creativity sufficiently for the sake of teamwork. Many researchers, however, have demonstrated that collaboration actually enhances creative thinking and outcomes and can leverage creativity because it compensates for one’s weakness and creates a synergy among members; furthermore, it can produce outcomes that are more than the sum of the parts.

When we look at students' collaboration processes, this tendency is obvious. One student is good at finding relevant resources and information; another is strong in generating exciting design concepts and strategies for a project, and yet another is proficient in expressing ideas and visualizing. Students often remark about the benefits of collaboration in brainstorming because they can dialogue about ideas and develop them, promoting numerous perspectives on projects. For such reasons, educators try to bring more collaborative practices into education so students can experience the benefit of collaboration for creative outcomes.

Kvan (2000) categorized three types of team work—coordination, cooperation, and collaboration—according to degree of shared authorship, resources, and compensation. Collaboration is the most advanced type in which participants create something that cannot be made as individuals. Constantino and Cho (2015) identified four strategies that can calibrate collaboration for creative outcomes: "(a) removed group-member hierarchy, (b) shared authorship, (c) use of visual communication techniques, and (d) design heuristic implementation" (p. 1). In fact, the necessity and motivation for collaboration exist in the contemporary design field because more complex tasks require creative input and feedback from specialized experts. Cross-cultural and transdisciplinary projects necessitate collaboration involving expertise, resources, and technologies. One way to cope with the challenges of the uncertainty of a rapidly changing society will be the collective team creativity which results from collaboration.

Divergent–Convergent Thinking

Design is an open-ended, vague, and ill-structured problem-solving process because it has no single correct answer and the solutions are not completely determined by given information. The creative interior design process entails both divergent and convergent thinking. Divergent thinking involves the ability to generate diverse, new, and original solutions to a given problem, whereas convergent thinking refers to the ability to suggest a single solution to a problem using logic and conventional rules (Guilford, 1959). Divergent thinking involves the expansion of thought and thinking without boundaries and from various perspectives. The characteristics of divergent thinking include flexibility, fluency (generating many ideas), and originality.

Also necessary for creative solutions, convergent thinking requires the capacity to blend various ideas into one best solution by summarizing, synthesizing, and decision-making in order to move into the next stage. Traditionally, convergent thinking has been perceived as the opposite of creativity, but recent researchers have found some evidence that creativity is a dual process involving both (Lazar, 2018). If one depends too much on divergent thinking, she or he may have difficulty in decision making and moving to the next stage; in contrast, if one lacks divergent thinking, she or he will likely have difficulty generating various ideas and maintain a single idea. According to Lazar (2018), a series of recent neuroscience studies using fMRI revealed that brain activities during the design process occur in multiple areas of neural networks and active interactions between hemispheres, implying that design creativity is unique among other types of creativity and entails both divergent and convergent thinking.

Prerequisites of "Creative" Interior Designers: Person

Then what are prerequisites for creative interior designers? Some people are naturally gifted with creativity, but creativity can be nurtured to a certain degree. Expertise and knowledge in the field are prerequisites to become creative interior designers, and these can be obtained through education. In addition, cognition and thinking style are malleable and can be acquired through training. The following offers a discussion of the four qualities prerequisite to the creative interior designer.

Expertise, Knowledge, Skill Set

Creativity involves the mental process of domain-relevant skills, including "memory for factual knowledge, technical proficiency, and special talent in the domain" (Amabile, 1994, p. 319). Knowledge of recent design trends, technology, system and structure, human behavior, regulations, and visual perception are all necessary for an interior designer. When one's expertise and knowledge accumulate to become a repository, the designer can easily extract appropriate information and resources. The repository can be explicit, resembling digital storage or actual file folders; but it could also exist inside the designer's head. Polanyi (1958) called it "tacit knowledge" that is difficult to describe or transfer to another person but significant in developing expertise. The content of the repository could be diverse, such as information on programming (e.g., needed types and sizes of rooms); it can be a gut feeling, intuition, or forecasting ability to determine what does or does not work well. Researchers found that more experienced designers have richer repositories and easily use them and generate ideas more effortlessly than novice designers. Although the amount of knowledge does not always correlate with creative outcomes, it is a necessity for creative thinking.

Visual communication skills—the ability to read, interpret, and produce drawing conventions—are also essential for creative interior design. Prerequisites for interior designers include understanding interior design information in space, communicating one's ideas with other designers or clients, and testing one's own idea for design development. In addition, knowledge of and the skills needed to use digital tools are essential in the contemporary design world. Examples of such tools include Computer Aided Design (CAD), Building Information Modeling (REVIT), Rhino, SketchUP, Maya and 3D Max.

Flexible, Adaptive, and Open-Mindedness

Flexible mind, the attitude to adapt new, different, and changing requirements, resembles the “adaptable mind” (Meneely and Portillo, 2005). Open-mindedness is one’s attitude in approaching design without prejudice or bias. Without flexibility, one is likely to hold a certain idea, prior knowledge, or past experience without trying other approaches or methods. The Torrance Test of Creative Thinking (TTCT), one of the most reliable tools to measure adult creative potential, is based on divergent thinking theory. It includes five components as indicators of creativity; flexibility (open-mindedness) is one of them along with fluency, originality, elaboration, and abstract thinking.

To illustrate, imagine that an interior designer has recently accepted a project to design a coworking space and that she had successfully completed the design of another such space five years earlier. If her thought is fixed on the past successful experience, she may approach the new project similarly, applying comparable space planning, finishes, and materials. If so, the new project may not be so successful and creative because a change may have occurred in technology, the generational character of the users, or work style; the work flow in the new coworking space may also differ. Adaptability to new ideas, concepts, and resources that fit the new project as well as up-to-date knowledge is essential. A successful idea for one coworking space may not be successful for another space; the idea may be already too popular, so no more novelty is elicited. Creative design entails knowledge and expertise, but it also necessitates flexibility, adaptability, and open-mindedness to approach the task with a new and fresh perspective.

Spatial Visualization

Spatial ability is the ability to imagine, manipulate, and produce spatial information. In interior design, the majority of information for communication is either in 2D or 3D format, such as orthogonal drawings (e.g., plan, elevation, and section), perspective, axonometric, renderings, and sketches. Although the subconstructs of spatial ability are diverse among researchers, it is typically known to consist of three subconstructs: mental rotation, spatial perception, and spatial visualization. Among the three, spatial visualization, particularly 2D to 3D visualization, has been revealed to predict the ability to produce original design (Cho and Suh, 2019). Spatial visualization involves “complicated, multistep manipulations of spatially presented information” (Linn and Petersen, 1985, p. 1484) and is most complex among the three subconstructs of spatial ability. Without spatial visualization, designers have difficulty visualizing and imagining objects spatially. Spatial visualization can be categorized into the following two levels: the fundamental level (to read and understand spatial information) and the advanced level (to imagine, transform, infer, and generate spatial information). To illustrate, the former requires knowledge of technical drawings and graphic conventions, such as knowledge of what thick lines and dotted lines mean in floor plans and section drawings; however, understanding only the meaning of such lines in drawing is insufficient in creative design. Designers must be able to imagine what the lines mean spatially and to infer the spatial relations and even the atmosphere created in the space. Designers create three-dimensional habitable spaces using drawings or sketches or by modeling digitally and manually before actually constructing them. Virtual Reality or Augmented Reality technologies can aid designer’s visualization along with other drawing and rendering software programs.

Intrinsic Motivation: Interest in Human Well-Being

Researchers have determined that along with domain-relevant skills and creativity-relevant skills, creative persons have strong intrinsic motivation, the most important factor in creativity among the three (Amabile, 1994). Intrinsic motivation is “the motivation to engage in a task primarily for the sake of the task engagement—because the activity itself is interesting, enjoyable, or personally challenging to the individual” (p. 320). It differs from extrinsic motivation, such as expectation of rewards or the desire to meet deadlines.

The intrinsic motivation of creative interior designers could be a deeper and genuine interest in human beings and the desire to create space elevating people’s quality of life. Interior design educators have emphasized “human-centered design” through profound understanding of human experience, behavior, and performance. Of particular importance is that interior designers create spaces where humans engage in everyday activities because people spend more than 87% of their lives indoors (Klepeis et al., 2001). Interior designers are advocates for public health, safety, and well-being.

Kijong Jeon, an interior designer and a professor at California State University, Chico, designed a multisensory environment for the improvement of the mood and behavior of cognitively impaired individuals with autism, the Community Opportunity for Vocational Experience (COVE) in Paradise, California (see Fig. 4). COVE is considered one of the pioneering works of design as therapy. He argued that design can serve as a passive therapeutic solution. At COVE, “fiber optic lighting, mesmerizing projections, undulating surfaces, and biomorphic furniture” (Design as Therapy, 2016) along with the sound of dropping water in a fountain and images projected on a multilayered wall create a both soothing and stimulating environment that encourages exploration of the space. Families of autism clients and administrators of the COVE reported many cases of positive changes of behavior (McGuire, 2009). In terms of his motivation, Jeon stated, “My work is completely life-affirming for me. It fills my heart. I love it” (<http://www.kijongjeon.com/cove.html>).

Creative interior designers require interest in the relationship between the characteristics of space and human response—the character of space that people like to approach or avoid and that people can concentrate or collaborate better and the reason for such reactions. The central idea is that the design decision should be based on a profound understanding of human needs. The

Figure 4 Multisensory environment for COVE designed by Kijeong Jeon. Photo credit: Kijeong Jeon.

moral, ethical, and wholehearted interest in human well-being and health appears at the summit of intrinsic motivation for creative interior designers.

Conclusion

Thus far we have discussed the multifaceted relationship between interior design and creativity and proposed a framework to understand domain-specific creativity in the field of interior design (see Fig. 5). We expect that this chapter will open a new discussion of the topic and add another perspective to creativity research.

Figure 5 Diagram for proposed framework for domain specific creativity of interior design.

Creativity has been the driving force behind the development and advancement of interior design. In the 21st century, we face an increasing number of complex issues and as yet unknown problems. These challenges include various environmental issues, such as global warming, resource depletion, air pollution, energy saving, and sustainability; social issues, such as changes in the family structure, lifestyle, generation gap, value conflicts, marginalization, poverty, and inequity; and technological issues, such as rapidly developing and changing technologies, robotization, and artificial intelligence. This highlights the importance of a strategic approach and human creativity that are more vital now than in any other time in history. These challenges eagerly await creative interior designers' creative mind and solutions.

PREFACE

The first two editions of *The Encyclopedia of Creativity* were enormously successful. They provided easily-accessible and trustworthy information about creativity and various topics related to creativity, such as innovation. The second edition, published in 2011, was named a 2012 *Outstanding Academic Title* by the American Library Association's Choice publication. The 3rd edition was inspired by the vast amount of new research about creativity. The field is expanding very rapidly. Much of this research is related to the increased complexity of each of our lives. Creativity helps each of us deal with such complexity. It also helps businesses, schools, and other organizations as the demands placed on them move faster and becomes more urgent. In addition, creativity provides new answers to such difficult problems as climate change, limited resources, religious and territorial conflicts, and poverty. For these reasons the *Encyclopedia of Creativity* includes articles that describe the creativity of individuals as well as organizations.

The *Encyclopedia* captures the full range of approaches to creativity. Creativity research is being conducted throughout the world in many different disciplines, including psychology, arts and humanities, health sciences, education, and business. The global interest is reflected in the number of authors throughout the world who have contributed to this edition as well as the topics covered.

Some countries such as China, Korea, Singapore and New Zealand have made understanding, teaching, and encouraging creativity part of their national goals. Europe proclaimed 2009 the year of creativity. The leaders of these countries recognize that their primary natural resource is the ability of their citizens and organizations to develop new products and innovative concepts. As competition becomes more and more intense, the business community in the United States is finally accepting the concept that creativity can contribute directly to the bottom line. A poll of CEOs in the United States by IBM's Institute for Business Value indicated that creativity is the most important characteristic being sought in new executive hires. We have responded to the increased interest in the business community by including more entries on organizational creativity.

The *Encyclopedia of Creativity* is designed to inspire further recognition of the personal as well as professional benefits that accrue from encouraging creativity. We know, for example, that individuals who are more creative are healthier and more adaptive, and in some instances may even have a longer life expectancy. We also know that many innovations and ways of solving problems have already led to incredible benefits, such as cures for diseases, improved technologies, and higher living standards for billions of people.

If we want a more creative world, then we must construct an environment that allows creativity to flourish. This requires knowledge that crosses disciplines. The increased quantity and diversity of research continues for the most part to be focused on a specific area of interest. Most scientific research is still released only in academic journals. There is still not a broad cross-fertilization of knowledge that enhances the development of new ideas. One of the axioms in creativity research is that breakthroughs often occur when information or concepts from one field are applied to a different one. Darwin's theory of evolution was partially inspired by his reading Malthus' theory of population growth and Lyell on geological change. Jean Piaget, noted developmental psychologist, borrowed heavily from biology and epistemology. Freud used a medical model to understand the psyche. Our hope is that readers will roam outside their usual areas of interest in a search for new ways of thinking. The comprehensive nature of the encyclopedia offers readers the opportunity to find new perspectives, which we hope will suggest fresh insights about themselves, their work, and their place in the world.

In the first edition we stated that there was enough known about creativity that it could be integrated into every level of our educational system. Unfortunately "teaching to the test" has become more prevalent in the United States while arts programs have been all too often dropped. We are obviously losing a great deal of the creative potential on this planet by leaving so many of our children uneducated and unable to cope with the

problems they face. The Encyclopedia continues to place an emphasis on education and cognition. It is our hope that teachers at the elementary and high school level will learn about their own creativity and how to value and encourage students. It is not always an easy task, but it can help enhance and even save the lives of some creative students who are at risk.

There has been some progress. The increased recognition of the importance of creativity in education was exemplified by its inclusion as number 8 in the top 20 competencies for teachers by the American Psychological Association. A 2019 Gallup poll in the United States reported that “Eighty-seven percent of teachers and 77% of parents agree that teaching approaches that inspire creativity in the learning process have a bigger payoff for students.”

Improvement is also evident at the college and post-graduate levels where courses in creativity are taught in many schools throughout the country. There is still a tremendous need for degree earning programs and specializations in creativity. The Torrance Center at The University of Georgia, Saybrook University, Buffalo State, and Drexel University are among the schools that currently allow a specialization in creativity studies. We hope that soon there will be many more universities and professional schools which include courses and specialties in creativity studies.

Audience

This Encyclopedia was designed for use by students of creativity, as well as researchers, teachers, scientists, coaches and consultants, architects and designers, trainers, managers, actors, writers, directors, painters and other individuals in the creative arts, inventors, therapists and other professionals who utilize creativity in their work. Anyone who is interested in learning more about their own creativity and the creative process can benefit from the articles presented here. None of this implies that there are quick and easy self-help answers - individual creative growth requires work, time, serious thought and a commitment to deeper understanding of the process. Still, creativity can be fun and it adds to the quality of life. Creativity can help us experience the highest levels of involvement in work and play that ultimately leads to great joy. Readers are encouraged to follow their own interests and inclinations in exploring these volumes.

Topics and Contents

Creativity is often viewed as a syndrome or complex. This perspective is described in various contributions to this volume, as are the various processes that are thought to make up or contribute to creativity. Other entries focus on particular methods and disciplinary approaches. In fact, one significant difference between this edition and the last one is that of sections devoted to the neurosciences and to technology and creativity. In addition, this edition is organized as a kind of hybrid, with overarching topics, including the two just mentioned, but also with various articles subsumed under Measurement and Personality headings. Specific topics include the following:

- There are reviews of a number of domain-specific areas, such as acting, dance, expressive arts, film, food, music, religion, science, sports, theater, and writing.
- Creativity and education are examined in articles about thought processes, such as developmental trends in creative abilities and potentials, the enhancement of creativity, intelligence, knowledge, play, prodigies, programs and courses, talent and teaching creativity.
- Cognitive aspects of creativity can be investigated in articles about altered and transitional states, analogies, attention, cognitive style, divergent thinking, flow and optimal experience, metacognition, metaphors, problem-finding, problem-solving, and remote associates.
- Those interested in business and organizational creativity can view articles about advertising with art creative visuals, business/management, creativity coaching, creativity exercises, entrepreneurship, group dynamics, innovation, leadership, organizational culture, organizational development, teams, and training, among others.
- Many articles examine the creative process across domains including areas such as discovery, emotion/affect, gender differences, incubation, inspiration, insight, novelty and paradigm shifts.

- The complex interrelationship between society and creativity is explicitly examined in articles about awards, conformity and conventionality, the creative sector and class of society, cultural diversity, the dark side of creativity, East vs. West, networking, social psychology, war, zeitgeist, and others.
- Personal and interpersonal creativity is discussed in articles relating to collaboration, family, life stages, mentors, networking, personal creativity and self-actualization.
- Because the encyclopedia focuses on scientific information about creativity, there are also articles that discuss concepts of creativity, definitions of creativity, expertise, longitudinal studies, researching art, artists and art audiences, research methods, phenomenology research and qualitative research.
- Articles which look at theoretical perspectives include behavioral approaches, chaos theory, componential models, economic perspectives, the evolving systems approach, the four P's of creativity, and implicit theories.
- The creative process is examined in contrarianism, climate for creativity, discovery, dreams, heuristics, invention, motivation/drive, multiple discovery, novelty, time and rewards.
- Mental and physical health and creativity are reviewed in mental health: affective disorders, health, mad genius controversy, schizophrenia and psychosis, stress, suicide, and transforming illness and visual art.
- Some subjects are grouped together in the Table of Contents. These clusters include the increasingly important Neurosciences and Technology, as well as Personality and Regional Creativity.

More than any other kind of book an encyclopedia is a collaborative effort. We thank our eminent panel of Subject Editors: Arthur Cropley, Vlad Glaveanu, Ning Hao, Maciej Karwowski, Aaron Kozbelt, Weihua Nui, Roni Reiter-Palmon, and Robert Weisberg.

Mark A. Runco and Steven R. Pritzker,
Editors in Chief

LIST OF CONTRIBUTORS

Ahmed M Abdulla Alabbasi

Arabian Gulf University, Department of Gifted Education, Manama, Bahrain

Oguz A Acar

Cass Business School, City, University of London, London, United Kingdom

Selcuk Acar

International Center for Studies in Creativity Buffalo State, State University of New York, Buffalo, NY, United States; and Buffalo State College, State University of New York, Buffalo, NY, United States

Patrick Adler

Department of Urban Planning, UCLA, Los Angeles, Canada

Sergio Agnoli

Marconi Institute for Creativity, University of Bologna, Bologna, Italy

Darija Aleksić

University of Ljubljana, School of Economics and Business, Academic Unit for Management and Organization, Ljubljana, Slovenia

Andrew P Allen

ADAPT Centre, Trinity College Dublin, Dublin, Ireland; and Department of Psychology, Bournemouth University, Poole, Dorset, United Kingdom

Julian B Allen

The Pennsylvania State University, University Park, PA, United States

TM Amabile

Harvard Business School, Boston, MA, United States

Ross C Anderson

University of Oregon, Eugene, OR, United States

Lionel Artige

University of Liège, Liège, Belgium

Matthijs Baas

Department of Psychology, University of Amsterdam, Amsterdam, the Netherlands

Donna Bacon

The University of New Mexico, Albuquerque, NM, United States

John Baer

Rider University, College of Education, Lawrenceville, NJ, United States

Baptiste Barbot

UCLouvain, Psychological Sciences Research Institute, Louvain-la-Neuve, Belgium; and Yale University, Child Study Center, New Haven, CT, United States

David Bashwiner

The University of New Mexico, Albuquerque, NM, United States

Roger E Beaty

Department of Psychology, Pennsylvania State University, University Park, PA, United States

Bianca Beersma

Department of Organization Sciences, Vrije Universiteit Amsterdam, Amsterdam, the Netherlands

Ronald A Beghetto

Mary Lou Fulton Teachers College, Arizona State University, Tempe, AZ, United States

Mathias Benedek

Institute of Psychology, University of Graz, Graz, Austria; and BioTechMed Graz, University of Graz, Graz, Austria

Maud Besançon

Université de Rennes 2, Rennes, France

Edward M Bowden

University of Wisconsin—Parkside, Kenosha, WI, United States

Richard Brower
Wagner College, Staten Island, NY, United States

Kris Byron
Managerial Sciences Department, Robinson School of Business, Georgia State University, Atlanta, GA, United States

Sarah Marie Catalana
Winthrop University, Rock Hill, SC, United States

Nur Cayirdag
Mohawk Valley Community College, School of Public and Human Services, Utica, NY, United States

Karen Chan Barrett
Sound and Music Perception Lab, Department of Otolaryngology—Head & Neck Surgery, University of California, San Francisco, CA, United States

Liang Chaoyun
National Taiwan University, Taipei, Department of Bio-Industry Communication and Development, Taipei, Taiwan

Ip Ching Yin
National Taiwan University, Taipei, Department of Bio-Industry Communication and Development, Taipei, Taiwan

Costin Chiru
University Politehnica of Bucharest, Bucuresti, Romania

Ji Young Cho
Department of Housing and Interior Design, Kyung Hee University, Seoul, Korea

Dowon Choi
Florida State University, Tallahassee, FL, United States

BT Christensen
Copenhagen Business School, Frederiksberg, Denmark

Kelly Christian
Lawrence School, Broadview Heights, OH, United States

MM Clapham
Drake University, Des Moines, IA, United States

Edward P Clapp
Project Zero, Harvard Graduate School of Education, Cambridge, MA, United States

Giovanni Emanuele Corazza
University of Bologna, Marconi Institute for Creativity, Bologna, Italy

Arthur Cropley
University of Hamburg, Hamburg, Germany

David H Cropley
School of Engineering, University of South Australia, Adelaide, SA, Australia; and School of Engineering, University of South Australia, Mawson Lakes, South Australia

Yi Cui
William & Mary, Williamsburg, VA, United States

Frédéric Darbellay
Inter- and Transdisciplinarity Unit, Centre for Children's Rights Studies, University of Geneva, Geneva, Switzerland

Tanja R Darden
Managerial Sciences Department, Robinson School of Business, Georgia State University, Atlanta, GA, United States

Subrata Dasgupta
School of Computing & Informatics, Emeritus, University of Louisiana at Lafayette, Lafayette, LA, United States

Tatiana de Cassia Nakano
Pontificia Universidade Católica de Campinas, Campinas, Sao Paulo, Brazil

Elena de Prada Creo
Faculty of Business and Tourism, University of Vigo, Spain

Constance de Saint-Laurent
University of Bologna, Marconi Institute for Creativity, Bologna, Italy

Annie S Ditta
Department of Psychology, University of California, Santa Cruz, CA, United States

Gabrielle Donnelly
Acadia University, Wolfville, NS, Canada

Viktor Dörfler
Senior Lecturer in Information & Knowledge Management, Department of Management Science, University of Strathclyde Business School, Glasgow, United Kingdom

CONTENTS OF ALL VOLUMES

<i>Editorial Board</i>	<i>v</i>
<i>Preface</i>	<i>vii</i>
<i>List of Contributors</i>	<i>xi</i>

VOLUME 1

A

Acting	1
<i>Paula Thomson and Maurice Godin</i>	
ADHD & Autism Spectrum Disorder	6
<i>Holly A White and Priti Shah</i>	
Advertising	12
<i>Mark Kilgour</i>	
Aesthetics	18
<i>Pablo PL Tinio</i>	
Alcohol	23
<i>Steven R Pritzker</i>	
Altered and Transitional States	29
<i>Stanley Krippner</i>	
Analogies	37
<i>Michael D Mumford and Robert W Martin</i>	
Ancient World Conceptualizations of Creativity	42
<i>Arthur Cropley</i>	
Animal Creativity	47
<i>Allison B Kaufman and James C Kaufman</i>	
Architecture	50
<i>Gabriela Goldschmidt</i>	
Artificial Intelligence	57
<i>Viktor Dörfler</i>	

Arts Bias	65
<i>Carla Rocavert</i>	
Art/Science	69
<i>Robert Root-Bernstein</i>	
Associative Theory	76
<i>Sandra W Russ and Jessica D Hoffmann</i>	
Asynchronicity	83
<i>Selcuk Acar</i>	
Attention	90
<i>Tara Zaksaitė and Vaibhav Tyagi</i>	
Attribution	96
<i>Nur Cayirdag</i>	
Avocations	103
<i>Michele Root-Bernstein</i>	
Awards	111
<i>Dean Keith Simonton</i>	
B	
Behavioral View of Creativity	118
<i>Mark A Runco</i>	
Bipolar Mood Disorders	122
<i>Dennis K Kinney and Ruth L Richards</i>	
Birth Order	129
<i>Toni Falbo and Shengjie Lin</i>	
Breadth of Attention	134
<i>Viktoria Tidikis</i>	
C	
Childhood Trauma: Shadow of Darkness	139
<i>Paula Thomson</i>	
Children's Creativity	144
<i>Mahsa Ershadi and Ellen Winner</i>	
Climate	149
<i>Michael D Mumford and Tanner R Newbold</i>	
Cognitive Style	154
<i>Øyvind Lund Martinsen, Geir Kaufmann, and Adrian Furnham</i>	
Collaboration	161
<i>Wendy Ross, Frédéric Vallée-Tourangeau, and Vlad Glăveanu</i>	
Commoditizing Creativity	167
<i>David H Cropley and Michelle L Oppert</i>	
Compensatory Advantage	172
<i>Sarah Marie Catalana</i>	

Competition	176
<i>Matthijs Baas and Bianca Beersma</i>	
Componential Models of Creativity	180
<i>Robert J Sternberg</i>	
Composers	188
<i>Aaron Kozbelt</i>	
Confucianism	195
<i>Charlene Tan</i>	
Consensual Assessment	199
<i>BA Hennessey, JS Mueller, and TM Amabile</i>	
Contrarianism	206
<i>Mark A Runco</i>	
Corporate Creativity	210
<i>Kevin S Mitchell and Roni Reiter-Palmon</i>	
Craft	215
<i>Paul Louis March and Vlad Glaveanu</i>	
Creative Class and the Creative Economy	222
<i>Richard Florida and Patrick Adler</i>	
Creative Destruction	226
<i>Frank Loesche and Ilaria Torre</i>	
Creative Environments, Conditions, and Settings	232
<i>David M Harrington</i>	
Creativity and Destruction	239
<i>Frank Loesche and Kathryn B Francis</i>	
Creativity and Perspective	246
<i>Haiying Long and Mark A Runco</i>	
Creativity and the Future	250
<i>Alfonso Montuori and Gabrielle Donnelly</i>	
Creativity Complex	258
<i>Mark A Runco</i>	
Creativity Gap	263
<i>Selcuk Acar</i>	
Creativity Models	268
<i>Dowon Choi, Vlad P Glăveanu, and James C Kaufman</i>	
Creativity Training	275
<i>Michael D Mumford and Samantha England</i>	
Criterion Problem	281
<i>Sue Hyeon Paek</i>	
Criticism	286
<i>Michael D Mumford and Mark W Fichtel</i>	

Crowdsourcing	291
<i>Oguz A Acar</i>	
Culinary Creativity	296
<i>Marc Stierand</i>	
Cultural Diversity	301
<i>Małgorzata A Gocłowska, Simone M Ritter, and Paul H. P. Hanel</i>	
D	
Dance	306
<i>Paula Thomson</i>	
Default Network	310
<i>Roger E Beaty and James Lloyd-Cox</i>	
Definitions of Creativity	315
<i>Arthur Cropley</i>	
Developmental Trends in Creative Abilities and Potentials	323
<i>Baptiste Barbot and Wida Rogh</i>	
Deviance	327
<i>Haiying Long, Jonathan A Plucker, and Mark A Runco</i>	
Dialectical Thinking: Further Implications for Creativity	332
<i>Rainer M Holm-Hadulla and Alexander Nicolai Wendt</i>	
Dignity	339
<i>Mark A Runco</i>	
Discovery	343
<i>Robert Root-Bernstein</i>	
Disruptive Innovation	350
<i>Ahmed M Abdulla Alabbasi</i>	
Divergent Thinking	356
<i>Mark A Runco</i>	
Diversifying Experiences	362
<i>Simone M Ritter and Malgorzata A Gocłowska</i>	
Diversity	368
<i>Alfonso Montuori</i>	
Domains of Creativity	377
<i>John Baer</i>	
Dreams	383
<i>Stanley Krippner</i>	
Drugs	390
<i>Steven R Pritzker</i>	
Dual Process	395
<i>Andrew P Allen and Kevin E Thomas</i>	
Dynamic Creative Process	400
<i>Giovanni Emanuele Corazza</i>	

E

Eccentricity	406
<i>Jeremiah Piña</i>	
Economic Perspectives on Creativity	411
<i>Lionel Artige and Todd Lubart</i>	
Education	417
<i>Ronald A Beghetto</i>	
Eminence	423
<i>Dean Keith Simonton</i>	
Emotion/Affect	427
<i>Sandra W Russ</i>	
Engineering: The Ultimate Expression of Creativity?	434
<i>David H Cropley</i>	
Enhancement of Creativity	440
<i>Jonathan A Plucker, Mark A Runco, and Mary A Simonsen</i>	
Entrepreneurship	447
<i>Liang Chaoyun and Ip Ching Yin</i>	
Everyday Creativity	455
<i>Ruth Richards and Terri Goslin-Jones</i>	
Evolving Systems Approach	463
<i>Jan M Stahl and Richard Brower</i>

Creativity consists of the capacity or state of bringing into being entities that are both new and valuable. Three cognitive functions responsible for creative constructions and effects are the janusian, homospatial, and sep-con articulation processes. During the course of creative activity, these processes operate both independently and in conjunction with each other. Dynamic interactions within and among the three processes produce emergent creative integration.

Empirical Studies

The creative cognitive processes were discovered through long term empirical investigations consisting primarily of extensive semi-structured research interview procedures (Int = verbatim quotations used) with consensually recognized highly creative achievers in the arts and sciences. Subjects have been, in literature: Nobel laureates (IntNL), Pulitzer (IntP) and other notable literary prizewinners; in science: Nobel laureates in physics, chemistry, and medicine or physiology (IntNLS) in the United States and Europe. Interview procedures were carried out over the course of the subjects' both long and short term creative projects and consisted of detailed objective examination of psychological processes in ongoing work and, where appropriate, past creative breakthroughs. Experimental assessments, as reported more extensively below, were also done with these and other creative subjects and non-creative controls (Rothenberg 1983, 1988b). Comparison control research interviews, carried out in the same semi-structured manner as with the creative subjects, were performed with less or non-creative matching cohort controls.

Documented accounts of breakthroughs and other creative productions of outstanding creators of the past were also systematically analyzed. The large body of evidence collected indicates that the three conscious and intentional processes, janusian, homospatial, and sep-con articulation, are used for creative work and thought in literature, art and science and, by extension, in various degrees in fields such as business, education, politics, sports as well as general creative problem solving and other everyday creative activities.

[☆] *Change History:* August 2019. Albert Rothenberg updated the text throughout the article.

This article is an update of A. Rothenberg, Janusian, Homospatial, and Sep-Con Articulation Processes, Reference Module in Neuroscience and Biobehavioral Psychology, Elsevier, 2017.

Janusian Process

The janusian process, most commonly operative in the early or inspiration phase of creative production, consists of actively conceiving multiple opposites or antitheses simultaneously. The term, based on the multifaced (variously possessing 2, 4, or 6 faces) Roman god Janus looking always in diametrically opposed directions, denotes conscious conceptualization during the creative process of simultaneously co-existing and operative opposite or antithetical ideas, propositions, or actions. Although seemingly illogical and self-contradictory, creators construct these conceptualizations in rational states of mind in order to produce creative effects. In art and literature these are responsible for early conceptions of plot, character, metaphor, organization, and design; in music for compositional and melodic construction; in science for creative breakthroughs, theorizing, and experiments. Depending on the level of development of a creative product, the janusian process also operates at later critical junctures and with practical solutions in a wide variety of fields.

Simultaneity of the multiple opposites or antitheses is a cardinal feature of the janusian process. Creators conceive firmly held propositions about the laws of nature, the functioning of individuals and groups, or the aesthetic and compositional properties of visual and sound patterns as simultaneously true and valid and not-true and invalid. Or, both opposite and antithetical propositions are entertained as concurrently operative. A person running is both in motion and not in motion at the same time, a chemical is both boiling and freezing, or kindness and sadism operate simultaneously. Previously held beliefs or laws are still considered valid but opposite or antithetical beliefs and laws are formulated as equally operative or valid as well.

These formulations within the janusian process are waystations to creative effects and outcomes. They are interacted and joined with other cognitive and affective developments to produce new and valuable products. Homospatial and sep-con articulation particularly operate as later unifying processes. Analogical, dialectic, inductive and deductive reasoning are applied concomitantly in the development of theories, inventions, and artworks.

The janusian process initially disrupts pre-existing contexts and conceptions. Highly surprising, even incredible and inconceivable, are propositions that the contradiction or opposite of well-grounded fact, theory, or actuality is simultaneously valid. Previously held ideas and systems of ideas are split apart and broken, even essentially destroyed. This disruption provides for the development of something new.

Janusian Process in Science

While working on an essay for the Yearbook of Radioactivity and Electronics in 1907, Albert Einstein had what he called “the happiest thought of my life.” This happy thought was the key to one of the most far-reaching scientific breakthroughs of the 20th and subsequent century: the general theory of relativity. The circumstances producing it were revealed in a document by Einstein himself—unpublished during his lifetime—and entitled by him, “Fundamental Ideas and Methods of Relativity Theory, Presented in Their Development.” (Einstein and ca, 1919)

Einstein had already developed the special theory of relativity, which holds that since the speed of light is constant for all frames of reference, perceptions of time and motion depend upon the relative position of the observer. He had been forced to postulate the theory, he said, to explain the seeming contradictions in electromagnetic phenomena: “[that] one is dealing here with two fundamentally different cases was, for me, unbearable.” [translations, Holton, 1973]

He felt strongly that he had to come up with a new and meaningful solution. For many years, he struggled to modify Newton’s classical theory of gravitation so that it could be encompassed within a broad relativity principle, but he lacked a specific physical basis for bringing together the seemingly different or antithetical choices of Newton’s theory and his own special theory.

All at once, Albert Einstein described, he conceived “his happiest thought”. It was: “For an observer in free fall from the roof of a house, there exists, during his fall, no gravitational field ... in his immediate vicinity. If the observer releases any objects, they will remain, relative to him, in a state of rest. The [falling] observer is therefore justified in considering his state as one of ‘rest.’”

Development of the general theory itself was highly complex, but the specific structure of the key step is clear. Einstein had consciously formulated the simultaneously antithetical construct that a person falling from the roof of a house was both in motion and at rest at the same time.

In physicist Niels Bohr’s first written formulation of his in-process theory of complementarity, the theory that has been a foundation for modern quantum physics, he stated that wave or else particle states of light and electrons, widely believed at the time to be completely conflicting alternatives, involved “no question of a choice between two different concepts but rather of the description of two complementary sides of the same phenomenon.” He then went on to formulate the full-blown complementarity theory, stated as follows: two descriptions or sets of concepts, though mutually exclusive, are both necessary for an exhaustive description of the physical situation. His key initial formulation of the complementarity idea was a janusian process construct that both light and electrons were phenomena with simultaneously antithetical wave and particle aspects (Rothenberg, 1987).

In order to assess the phenomenon of scientific creativity empirically, I conducted a study of 45 Nobel laureates in physics, chemistry, and medicine or physiology located throughout the United States and Europe. This consisted primarily of detailed semi-structured interviews focused on the laureates’ creative scientific discoveries compared with the same procedures carried out with a control group of highly intelligent but non-demonstrably creative university faculty scientists. The following table shows the use of the janusian process consisting of conception of simultaneous opposites leading to outstanding creative discoveries of the Nobel laureate test subjects (Table 1).

Table 1 Janusian process^a

<i>Nobel laureate</i>	<i>Opposite factor</i>	<i>Opposite factor</i>	<i>Janusian conception</i>	<i>Discovery (discoveries)</i>

Janusian Process in Literature, Art, and Music

(IntPP) Playwright Arthur Miller disclosed to me that he had come up with the specific idea for the play “Incident at Vichy” while traveling through Germany: “Driving on the autobahn, I suddenly felt amazed and overwhelmed at how beautiful Germany had become.” He conceived of writing a play that would simultaneously express the opposites of the beauty of modern Germany and Hitler’s destructiveness. “And then, I remembered a story I’d been told about a sacrifice made by an Austrian nobleman for a Jew in a Nazi official’s waiting room.” He developed the story of the political simultaneously antithetical sacrifice in his play.

Poet James Merrill had been home thinking about a past incident in which a horse had appeared at a lonely desert site, when it occurred to him, he told me, that horses are animals who “renounce their own kind in order to live our lives.” The idea that horses live human lives, that they are antithetically both beast and not-beast and human and not-human simultaneously, generated the poem, “In Monument Valley,” with the central image and theme of a happy and intense relationship between a young person and a horse, followed by a sad, resigned separation.

Artist Jackson Pollock’s early drawings and paintings were strongly based on the styles of Thomas Hart Benton, Diego Rivera, and Jose Clement Orosco. During the summer of 1939, when he was improving from alcoholism and mental illness, he created his first abstract expressionist paintings, becoming the so-called father of that style. These revolutionary artworks, he later explained to an art critic, were based on his conception of both obscuring an image and expressing it at the same time, a janusian process formulation.

In music, the writings of composers from early to more recent modern times have stipulated simultaneous oppositions regarding germinal aspects of their compositions. Renaissance composer Claudio Monteverdi described his method of producing slow and fast tempos simultaneously as a means of conveying the “contrary passions aroused by war, prayer, and death.” Modern composer and conductor Leonard Bernstein described the constant use of “contradictory forces, chromaticism and diatonicism, operating at the same time.” Composer Arnold Schoenberg conceived the simultaneous use of the opposites of consonance and dissonance in his musical creations and compositional instructions to disciples.

Homospatial Process

Mental representation of space is potentially more far reaching, extreme, and diverse than any physical actuality. The homospatial process responsible for many types of creative results involves mental representations that defy or go beyond objective or actual physical space. This process consists of actively conceiving two or more discrete entities occupying the same space or spatial location, a conception leading to the composition of new integrations and identities. In conscious mental space, creators superimpose, interpose or otherwise bring together shapes, patterns, written words, dimensions, distances, and other concrete entities. Subjectively, eyes closed or open, other physical receptors attentive or inattentive, the resulting mental image totally fills the conceptualized perceptual space. Any sensory modality may be involved: visual, auditory, tactile, kin-aesthetic, olfactory, and gustatory. The imaginary location may be considered to be the “mind’s eye”, “mind’s ear,” “mind’s taste,” etc.

Once the discrete entities in the homospatial process are consciously brought together, the mental conception is a rapid, fleeting one. In the creator's mind, the superimposed and interposed elements begin immediately to interact and produce new identities, including new ideas. These ideas constitute solutions to scientific and other problems, and in the arts they consist of created metaphors, plots, visual themes and constructions, musical passages, and other integrations.

Not a matter of simple combination, unconscious condensation, conceptual blending (Turner and Fauconnier, 1999) or of the discrete entities considered in stepwise or analytic fashion, the homospatial process involves unstably related entities that interact. Ordinarily used later than the janusian process but, as in an oxymoronic metaphor such as Hart Crane's "penniless rich palms" from his *Voyages II*, both processes may operate early and concurrently. Newness in the created results produced by the homospatial process begins with creators' breaching the physical percept that two or more discrete entities cannot in actuality occupy the same space. The valuable aspect emerges from rapid interactions among the superimposed and interposed elements.

Homospatial Process in Mathematics and Science

Mathematician Henri Poincaré described the mental conception of a coalescing and spatial superimposition of mathematical formulations which led to the discovery of a crucial aspect of his famous Fuchsian functions: "One night, I took some black coffee, contrary to my custom, and was unable to sleep. A host of ideas kept surging in my head; I could almost feel them jostling one another, until two of them coalesced, so to speak, to form a stable combination. When morning came, I had established the existence of one class of Fuchsian geometric series. I had only to verify the results, which only took a few hours."

(IntNLS) Chemist William Lipscomb described to me one of his Nobel Prize discoveries in boron chemistry as arising from a superimposed image of a hydrogen atom and a three center chemical bonding: "What I mean," he said, "by the superimposition ... this hydrogen comes over here [points to formula], and interchanges with this vacancy. I saw the previous three center bond there, and then it came loose and twisted around. I did that in my head and it became perfectly clear in the nuclear resonance study I published. I had the right structure."

Through the controlled empirical investigation of the creative discoveries of the science Nobel laureate subjects described earlier, the evidence on the following [Table 2](#) documents the use of the homospatial process in critical Nobel laureate scientific discoveries.

Homospatial Process in Literature, Art, and Music

The homospatial process is a prime factor in the production of poetic metaphors. An author experimental subject was, for instance, sitting at his desk writing a poem. To produce what was to be a central metaphor, "the branches were handles of

Table 2 Homospatial process^a

<i>Nobel laureate</i>	<i>Discrete entity</i>	<i>Discrete entity</i>	<i>Homospatial conception</i>	<i>Discovery</i>
Donald Glaser	Bathtub	Self taking pictures	Superimposed in orbit–superheating	Bubble chamber
Joshua Lederberg	Self	Bacterial cell	Superimposed self and cell	Bacterial conjugation
Owen Chamberlain	Velocity determining counter	Threshold determining counter	Superimposed– reduced material	Pickle barrel or secret weapon counter
Walter Gilbert	Roll of soiled toilet paper	DNA molecule	Continuous replication	Rolling circle model of genetic replication
Glenn Seaborg	Uranium	Rare earths	Subshell characteristics	Actinide concept of heavy elements
Dudley Herschbach	Energy transfer	Non-energy transfer	Wave node	Bond breaking and making
Walter Alvarez	Large meteor	Volcano eruption	Coal smoke cloud of darkness	Dinosaur extinction

Pierre-Gilles deGennes	Snake	Noodle	Movement of clusters in a cell	Reptation
Joseph Murray	Grand piano	Old upright piano	Transfer location	Kidney transplant
Jean-Marie Lehn	Individual shapes or forms	Other individual shapes or forms	Superstructure	Chemical self-representation
William Lipscomb	Hydrogen atom	Three center bond	Chemical bondings	Borane structure
Norman Ramsey	Atoms in a box	Atoms in a tube	Atoms in a bottle	Hydrogen maser

^aThe first column specifies the Nobel scientist; the second and third columns indicate the specific discrete scientific entities; the third column designates the superimposition of the discrete entities in a homospatial conception; the fourth column specifies the creative scientific discovery. (Rothenberg, 2014)

stars," he had become attracted early to the words "handle" and "branch" because of their shared sound qualities—the assonance or shared "an" sound in the center of each—as well as the shared overall shapes of the wooden objects themselves. He then superimposed these words and their concrete images in his mind's eye; he brought them together because he felt they ought to be together. In the next fleeting moments, he asked himself when in reality they were the same, and also fleetingly experienced a vivid impression of the letter "a" overlapping in the two words. At that point the idea of stars was generated. Associational or analogical ideas of the country (or park) at night did not generate the metaphor; it was derived directly from the homospacial process conception that provided both the real scene and sound qualities that unified the words and their meanings.

In the creation of another type of metaphor, "the tarantula rays of the lamp spread across the conference room", this author in a detailed interview remembered thinking about writing a poem about a vacation in the tropics and, among the various thoughts and words that came to mind, he became interested in the sound similarity between the words "tarantula" and "lamp." He then actively superimposed mental images of the spider and a light source together, along with images of the letters in the words, because he felt these ought to be together. After mentally visualizing spidery light radiating out from the central source of the superimposed images, he thought of the metaphor, "tarantula rays of the lamp." Deciding to elaborate that fragment with a suggestive context, he next conceived of "conference room". Once the entire creation was constructed, he thought of overtones such as wars in the tropics, the idea of the slow crawl of a tarantula in contrast with the dazzling speed of light, and experiencing an awesome type of beauty, he was pleased. With both poetic creations, the author visualized a vague scene as well as found the answer in words. Later, he visualized more fully developed and vivid scenes similar to the ones experienced by a reader or audience, and he composed the metaphors as well as descriptions of the scenes into several poems. The fully visualized scenes did not, however, produce the metaphors, they mainly added to the poet's feeling of the aptness of his creation.

Sculptor Henry Moore indicated the crucial role of a homospacial process in the creation of sculptural works of art as follows: "This is what the sculptor must do. He must strive continually to think of, and use, form in its full spatial completeness. He gets the solid shape, as it were, inside his head—he thinks of it, whatever its size, as if he were holding it completely enclosed in the hollow of his hand. He mentally visualizes a complex form from all round itself; he knows while he looks at one side what the other side is like."

In music, auditory metaphors and new musical patterns and themes develop from homospacial process constructions. Ludwig van Beethoven described that "the underlying idea [of a musical work] rises ... grows, I hear and see the image in front of me from every angle, as if it had been cast." Robert Schumann said, regarding his composing process, "certain outlines amid all the sounds and tones ... form and condense into clear shapes."

Interaction Between Janusian and Homospacial Processes

(IntPP) James Merrill's previously described janusian formulation of a horse as both beast and human simultaneously for the poem, "In Monument Valley" was subsequently integrated into a particular central poetic metaphor by a homospacial process conception. A horse and human being were conceived as occupying the same space; that led to the construction of the following poetic image: "Stillnesses were swarming inward from the evening star/ Or outward from the buoyant sorrel mare/ Who moved as if not displeased by the weight upon her./ Meadows received us, heady with unseen lilac./ Brief, polyphonic lives abounded everywhere. With one accord we circled the small lake."

The resulting poetic image was neither a centaur, a mythical entity that is part human and part horse, nor was it some other mixture or combination of horse and man.

Experimental Evidence for Janusian and Homospacial Processes

A tendency or capacity for the use of the janusian process among proven and potentially creative persons, manifested by very rapid opposite responding on word association tasks, was experimentally identified (Rothenberg, 1978). Standard Kent-Rosanoff word association tests were individually administered to 22 Nobel laureates in science (physics, chemistry, medicine or physiology) and to rated-as-creative Yale College students (Rothenberg, 1983). Control groups consisted of matched but rated-less-creative students and high IQ psychiatric patients. Test instructions were to give the first word that came to mind in response to a standardized list of word stimuli and both speed and content of response were electronically recorded. Results signified, for the most creative subjects, formulation of simultaneous or virtually simultaneous opposite associations. The statistically significant highest number of extremely rapid opposite responses (averaging 1.1 to 1.2 seconds) were given by proven creative subjects, the Nobel laureate group, and the next highest by the rated-as-creative Yale students.

Experimental assessment of the creative action of the homospacial process, assessing the stimulus effects on art and literary metaphors of ten concrete representations of mental constructions consisting of a series of ten transilluminated superimposed component slide images, were carried out with artist and writer subjects (Rothenberg, 1988b). Control halves of each group were also asked to produce art or literary metaphors in response to side by side slide presentations of each of the individual component images. Results were the statistically significant greater production of both creative literary metaphors by writer groups and creative pastel drawings by artist groups in response to the superimposed images in comparison with responses to the side by side presentations seen by the controls. An example of a test superimposed stimulus image,

Figure 1 The first slide pair, separate (B and C) and superimposed. (A) Photograph of colored slides as projected superimposed onto the viewing screen. Photographs of individual color slides.

consisting of nuns in front of St. Peter's and racing jockeys is shown in [Fig. 1](#). An experiment using shorter stimulus exposure times to facilitate more rapid mental superimposition and manipulation produced similar results. ([Rothenberg and Sobel 1981](#))

Superimposed Experimental Images

With highly talented award winning artists, another experiment was carried out to assess whether the results of the previous experiments could have been due to stimulus presentation effects. Results were that presentation of test superimposed images in controlled comparison with foreground-background (gestalt) displays of the same subject matter yielded significantly higher rated creative products. ([Rothenberg, 1988b](#))

Sep-Con Articulation

The sep-con articulation process consists of conceiving or constructing separation (sep) and connection (con) concomitantly. The term derives from the root meaning of articulation as joining, joint, to join, and the commonly applied phrases, "being articulate" or "an articulate speaker." Speaking smoothly and continuously, the articulate speaker joins words and ideas together and keeps them clearly separate at once. In creative work and activity, the creator uses such concomitant separation and connection, the process of sep-con articulation, in many different dimensions—conceptual, perceptual, affective, and physical. It differs from blending ([Turner, Fauconnier, 1999](#)), fusion, combining, connecting or connectivism alone, in that, with the sep-con articulation process, the creator brings together separate component elements that retain their individual characteristics.

Integration characterizes created works and is a crucial factor in their positive value. The process of sep-con articulation, because of discordance of concomitant separation and connection, leads as with conflicting elements of the janusian and homospatial processes, to dynamic interaction and the emergence of integration. Separate individual elements retaining their identities contribute to the functioning of a large or small whole connected system. This integrated whole has qualities not present in any individual element or factor; it is greater than the sum of its parts.

When creators produce new ideas, procedures, experiments, neologisms, plot themes, artistic or musical patterns, they integrate them into a created result by means of the process of sep-con articulation. Integration, contingent organicity, and usefulness produce the value aspect of creations in all fields, the sciences and arts as well as the products of everyday ingeniousness. Newness or originality alone does not guarantee successful application or appreciation. New elements, forms, or mechanisms must have articulating concomitance with previously existing elements, forms, or mechanisms in order to become creations. New factors must have connections with comparable past ones. Creative new experiments, for example, are always connected to some degree with existing canons of scientific knowledge, creative new post-modern sculptural or painting styles are in some part connected with

realism, op and pop art, action painting and many other previous approaches. Joyce's and Shakespeare's literary creations are connected, both in subject matter and form, with previous works of literature and life events. New factors, therefore, which are clearly distinct and separate are at the same time connected in some measure with the past. Creations are articulating concomitants of new ideas, objects, and structures with aspects, sometimes totalities, of the past.

Sep-Con Articulation in Science

(IntNLS) Physicist Norman Ramsey conceived the "Separated Oscillatory Field Method" which provided critically important high resolution in atomic and molecular spectroscopy for the production of the most precise atomic clocks. He disclosed that he had been working on making a connection between a short and longer magnetic field apparatus and had first conceived that the nature of the field was crucial and *also* that it would have to be uniform. Then, deciding later all at once that the uniformity of the field itself was less important than the separated beginning and ending, he conceived a solution in which the distinctly separated "bits," were concomitantly connected through oscillations. The interactions between the concomitant separations and connections produced mutual modifications and a creative outcome. He said to me, "[the connecting oscillations produce] a short, much stronger field at the beginning and a short, much stronger field at the end, and then the middle part averages out."

(IntNLS) Chemist Jean-Marie Lehn is responsible for the creation of the field of supramolecular chemistry, developments in which have made important contributions to nanotechnology, work with catalysts and catalysis, pharmaceutical therapies, and drug delivery. "Supramolecular chemistry," he said to me, "has to do with the designed manipulation and use of weaker interactions, weaker forces, compared to intramolecular ones, which glue molecules together and allow you to construct large architectures."

He developed supramolecule structures from conceiving concomitant separation and connection: "What one wanted was building a three dimensional negative image in space ... This is a cavity, a 'crypt;' so there are 'cryptands', 'cryptates', and so on The hidden aspect is important because the interactions of the outside species with what is hidden determines both the properties of what is inside ... and also what's outside".

Table 3 denotes the results of the subject Nobel laureate groups' use of sep-con articulation in attaining their creative discoveries as determined through the controlled interview study described earlier.

Sep-Con Articulation in Art, Literature, and Music

In literature, the development of characters results from the process of the author's sep-con articulation of self. Created literary characters are neither simply representations of the writer's personality or life history nor combinations of these factors with those of other persons, real or imaginary. Throughout the course of writing a novel, play, or poem, the author concomitantly connects and separates his own emotions, personality characteristics, and experiences with the fictional characters being created. There is continual interaction of features of the author's self and the developing portrayal.

The sep-con articulation process also operates in the creation of poetic form. (IntPP) James Merrill created a central metaphor, "a mastermind kept track above the mantel" of the poem entitled, "18 West 11th Street" through concomitant separation and connection of words pertaining to his self and the destruction of the eponymic house. It was the street address of a brownstone house in Greenwich Village that Merrill lived in as a child. The house much later was actually accidentally blown up by a revolutionary group called "The Weather Underground" during a project of making bombs in the basement.

The "mastermind" mirror in the poem allows a passing through in imagination of both the poet's childhood images and the world of the Weather Underground. During the process of creation, he wrote more than twenty-five different versions of these lines. Before the final step, he focused on an off-rhymed word-pair, "mental" and "mantel." Then, in the process of sep-con articulation, he conceived the metaphoric word "mastermind" by taking from "mental" the separate idea of "mind" and connecting it concomitantly with the idea of saboteurs or masters from another portion of the poem. He was aware at the same time of separating out the initial consonants and vowels of the word pair "mental" and "mantel" and connecting them into an effective sound similarity: both alliteration (m sound) and assonance (en/an sound). The mastermind metaphor, effective in both structure and meaning, became an aesthetic integration in the poem.

In his diary, in 1892, expressionist artist Edvard Munch described a visual hallucination of a bloody red sky that provided the inspiration of emotionally charged elements that he distinctly integrated by means of the sep-con articulation process (and, in a lesser other way, the superimposition of the homospatial process), into the famous artwork, "The Screech" or "The Scream" (Fig. 2). Over a period of more than a year, he several times progressively connected and separated himself and his hallucination, as represented by a human subject viewing the sky, with nature.

He first did a drawing showing a solitary man leaning far at the back in profile over a bridge and looking spectator-like at the sky and a boat on a small lake, then later he did a painting depicting the leaning still-profiled man located right at the front of the scene. In the next two charcoal drawing versions, he put a round bowler hat on this same spectator man in profile. After that, in an ink sketch much later in that year, he depicted the then bowler-hatted man facing fully forward and matched the rounded shape of the hat with the curved lines of both the sky and the contours of the man's body – a probable result of conceived superimpositions of the homospatial process. In the final version, first done as a lithograph and later as a painting, he developed critical aspects of the image by presenting the man concomitantly separated and connected with the nature scene. The forward-facing man was portrayed

Table 3 SEP-CON articulation process^a

<i>Nobel Laureate</i>	<i>Functional Separate</i>	<i>Functional Separate</i>	<i>Connection</i>	<i>Sep-con Articulation</i>	<i>Discovery</i>
Georges Köhler	Antibody lymphocyte cell	Myeloma cell	Joining	Unitary cell	Monoclonal antibody
Max Delbrück	Physics	Biology	Phage study	Phage genetic replication	Molecular Genetic biology
	Bacterial host	Phage virus	Interaction	Resistant bacterial variant	Genetic replication
	Minimal error	Investigative factor	“Nailing down”	Principle of limited Sloppiness	Phage biology
Salvador Luria	Resistant bacteria	Non-resistant bacteria	Uniform agent	Genetic probability distribution	Lurian Distribution
David Baltimore	Virus RNA	Tumor cell RNA	RNA polymerase	Messenger and genic replication	Reverse transcriptase
David Hubel	Stimulus	Visual cortex cells	Line of orientation	Orientation selectivity	Functional organization of the visual cortex
Werner Arber	Restriction	Modification	Enzyme	Restriction/modification	Hereditary Mutation in bacteria
Allan Cormack	Inside measurements	Outside measurements	Connected Images	Axial Tomograph	CAT Scan

with no hat but with an oval screaming mouth. Both the red sky and man's body contained differently oriented ovoid types of curves. Mouth, sky, and body all were in this way separated and connected concomitantly. He thereby produced a universal pictorial metaphor, a metaphor verbally described as "the scream of nature," that provides much of the integrated aesthetic power of this painting.

The process of sep-con articulation operates throughout musical creation. Just as the articulate and creative speaker brings phrases and ideas together smoothly and in continuous flow while concomitantly separating these phrases and ideas clearly, created music brings rhythms, themes, instrumental effects, and other sonorities together smoothly while constantly separating these elements. It produces the organic integration of music. Classical composer Paul Hindemith, using the analogy of seeing a heavy flash of lightning in the night, described the musical operation of the homospatial and sep-con articulation processes both together as follows:

"Within a second's time we see a broad landscape, not only in its general outlines but with every detail We feel that not even the smallest leaf of grass escapes our attention. We examine a view, immensely comprehensive and at the same time immensely detailed Compositions must be conceived the same way. If we cannot in the flash of a single moment, see a composition in its absolute [connected-A.R. added.] entirety, with every pertinent detail in its proper place, we are not genuine creators.

Phases of Janusian, Homospatial and Sep-Con Articulation Processes

All three processes function in creation individually as well as in conjunction with each other. There are four phases in the creative process that occur over extended periods of time or are else condensed into a very short span such as sometimes occurs with sudden breakthroughs and insights. Ordinarily, the creative thinker uses the janusian process earlier than both homospatial and sep-con articulation processes. All three begin with an overarching first phase consisting of the deliberate motivation to create; nothing new and valuable is created without the intention to do so. Both the intentional goal and the area chosen for creation always have emotional (including aesthetic) importance for creators themselves. Combined emotional and ideational motivation provides the drive to conceive the inconceivable and use other daring and unusual cognitive modes in the next phases.

In the second phase for each of the three processes there is a deviation from the customary. The creator using the janusian process focuses increasingly on seemingly unreconcilable poles of opposition or antithesis. Scientific creators, highly knowledgeable about their fields, at this time begin to break away from widely, even strongly, held precepts of approach and content. In art, literature, and

music, knowledgeable creators' choices of particular opposing elements of form or content in their works differ in some fashion from those of previous writers, artists, or composers. This is the beginning of a departure from the known and accepted that ultimately produces newness in the created product. Creators' gradual and continuing development of specific thematic poles and aspects serves to separate and isolate critical factors in the area of investigation, technology, or aesthetic production.

In both the homospatial and sep-con articulation processes, in the second phase, creative thinkers choose entities that, while they differ both singly or in multiples from the usual, have functional or structural similarities with each other. For the visual artist it may be repetitions, juxtapositions, contraries, or oppositions in shape and color, for the writer (especially the poet) and musician it may be sound, communal and physical relationships, and for the scientist it is functional, conceptual, or physical relationships within the problem being worked on.

In the third phase of the janusian process, creative thinkers conceive multiple opposites or antitheses as operating simultaneously. It is here that ideas constructed sometimes seem surprising to the creators themselves. At first unthinkable, even disjunctive, are postulates that antithetical factors co-exist or operate together, or that something that has existed or was known previously continues to operate together with its diametric opposite. Also, one pole or portion of an opposite or set of opposites may up to then have been in conscious focus while others have been dimly held at the periphery. Conscious positing of the simultaneous validity of these opposites may become a sudden and enthralling experience, producing a sense that is sometimes described as "something coming out of the blue" or projectile. With respect to newness, the simultaneity of opposition is a phenomenon experienced as being out of time. As it is out of time, or out of temporal succession, it is discontinuous with previous factors and therefore distinctly new.

Distinct cognitive abilities and proclivities are involved in the janusian process and emotional underpinnings interlock with these. When emotional involvement involves meaningful conflict, it especially jibes with the cognitive tendency in the janusian process to focus on opposites and antitheses and bring these together simultaneously. The simultaneous opposition and antithesis with its retained conflict among composing elements is isomorphic with emotional conflicts, both open and hidden, for all types of creators.

In the third phase of the homospatial and sep-con articulation processes, creators bring together the collected functionally or structurally similar elements. With the homospatial process, they are superimposed or interposed in the same mental space; with the sep-con articulation process they continue to be separate identities while they are connected. Creators bring together these entities because they conceive that they ought to be together. The conception deviates from previously known composite structures in a manner similar to the types of deviation of the janusian process. There are several reasons for conscious deviation, many of which are emotionally driven and may be unique to the particular thinker.

In the fourth phase, both the homospatial and sep-con articulation processes lead individually to partial or complete integrations. Also, they operate together with the janusian process, modifying it and integrating the simultaneous opposites into the full dimensions of the artwork, theory or discovery. Stepwise logical and synthesizing mental processes operate in this phase as well. Not to be minimized in any way, specific skills are critically important, such as, in science, high intellect and intelligence, observational and deductive capacities, and knowledgeable attention to canons of empirical validation. In art, music, and literature, high level skills with language, sound and pictorial relationships are necessary to produce the fully developed aesthetic product. Other specific skills are distinctly necessary for creativity in various other fields.

Aspects of both janusian and homospatial processes have features in common with sep-con articulation. Opposites and antitheses in the janusian process are both separated and connected when simultaneously posited. In the homospatial process, discrete separate entities become connected within the same space. Sep-con articulation is used conjunctively throughout all phases of the creative process, interacting and interlocking with the various phases of both janusian and homospatial operations. Creators use it independently primarily in the fourth phase construction of the completed work. Overall, the sep-con articulation process has a biphasic configuration. In the early aspect, the person who is motivated or "inspired" to create takes in emotionally laden stimuli, experiences, and concepts. Analogous with the literal meaning of the term inspiration in breathing or respiration, the taken-in contents are, like elements in inspired air, modified. Mentally, these modified contents interact both consciously and unconsciously. Not simply expelled or expired, through such postulated mechanisms as unconscious breakthrough or as catharsis, however, the contents are consciously sep-con articulated. Similar to the everyday creation of human utterance in which inspired air is articulated by the voice apparatus and the brain to construct words and language, the sep-con articulation process modifies initially taken-in inspirations in an extended final phase.

Glossary

Analytical psychology A psychological science, developed by Carl Gustav Jung, that grew out of psychoanalysis and includes theory, research, and practice.

Archetypal image A representation, or motif, of an archetype that has infinite manifestations. The produced archetypal image gives a voice to the archetype itself and is commonly found in fairy tales, legends, religion, mythology, dreams, and art. Also referred to as a primordial image.

Archetypes Limitless instinctual forms, not yet ideas or representations, within the collective unconscious thought to be passed down through the ages and found in all cultures. Archetypes are not visible until an image is created.

Autonomous complex An emotionally charged part of the psyche that usually includes material from consciousness as well as the unconscious. Forms the connection between the personal and archetypal parts of a person. Autonomous complexes, which are many, include the creative complex.

Collective unconscious The second layer of the unconscious, preceding the personal unconscious, which houses the archetypes (often used interchangeably with the concept of archetypes, defined above). Considered the reservoir of great art.

Individuation The cornerstone of Jung's theory of personality development. The process is lifelong and the goal, which is attainable only in stages and not in total, is to become whole, complete, and truly individual. Making great art is linked to this process.

Personal unconscious The first layer of the unconscious that stores traumatic memories, experiences, and ideas that are unique to the individual's past. This layer of the unconscious precedes the collective unconscious.

Symbol The greatest conceivable expression for an idea; the idea cannot be produced in a better way. Symbols can be recognizable connections to archetypes, but their actual meaning is unknown. Great art is truly symbolic.

Wholeness The ultimate form of expression of all parts of the personality to one's self, others, and nature. Being psychologically whole equates with health, and health equals creativity—the goal of individuation.

Carl Gustav Jung—The Man

Carl Gustav Jung was born on July 26, 1875, in Kesswil, Thurgovie, Switzerland (also spelled as Kesswil, Thurgau, in other biographies). His family was economically poor. Jung's father, a Doctor of Philosophy, worked as a pastor in the Swiss Reform Church and was also an Oriental and classical scholar. His father was described as quite conventional in his religious beliefs, from which Jung later strayed. By some accounts, Jung believed his father was weak. Jung's mother was thought to be inconsistent and divided in

[☆] *Change History:* November 2019. Keri Jones updated the text throughout the article.

her thoughts. She often contradicted herself. He seemed to identify with her in many ways, especially regarding his intensely complex inner world and the two strong parts of her personality that opposed one another.

This opposition was part of Jung's experience of himself (and later a central part of his theory of personality). When Jung was 3 years old, his mother was hospitalized for several months, probably due to problems in her marriage that continued throughout his youth. Over time, Jung developed mixed feelings for his mother. Jung was a highly sensitive, curious, and bright child who had several bouts of physical illness. He was acutely aware of his thoughts, feelings, and surroundings. Growing up in the country afforded him a great deal of pleasure and a place for exploration. He enjoyed the beauty of his homeland and was in a frequent state of discovery about the world around him.

The beauty and brightness he experienced was contrasted by several dark experiences that followed him for much of his life. The dark experiences included themes of death, religious activity, dreams, and fears. This duality serves as the cornerstone for much of his theoretical frame. Jung took playing quite seriously, and playing alone became a constant for Jung as he was an only child until the birth of his sister when Jung was 9 years old (he had a brother who died 2 days after his birth, 2 years preceding the birth of Jung).

He was quite interested in Eastern religion, mythology, and nature as a young boy. Being alone allowed him the space to ponder the many questions he had about life, especially religion. Some believe that the materialization of analytical psychology was his way of finding a replacement for religion. He did not have any companions that he trusted enough to share his meaningful ideas or questions, and thus he felt even further isolated.

School for Jung was wrought with ups and downs. At times he was strongly engaged and at other times he was disengaged. His interest varied depending on experiences he had with other students and his teachers, as well as their perception of him.

After much deliberation, Jung decided to attend medical school. He struggled with this decision because he originally wanted to study natural science or the humanities. Psychiatry, which became known to him late in his academic career, was his final choice as a specialization. He found his university experience exciting and challenging. In addition to medicine he was able to continue his study and exploration of theology, philosophy, and Eastern theories.

After finishing school in 1900, Jung moved to Zurich, Switzerland, where he lived for the rest of his life. He began training at a psychiatric hospital in the city. For the first 6 months he lived in the hospital, immersing himself with psychiatric literature and learning firsthand what the experience was like.

Here he became fascinated with the minds of patients with many disorders, including schizophrenia. Many of his theories originated from his work in the hospital. He became rather disillusioned by the way patients were treated and began to experiment with alternative therapies. This disillusionment led him to the work of Sigmund Freud.

Jung published his first paper in 1902 and began lecturing at the university in 1905, meanwhile building a private practice in Zurich. In 1907 he met Freud. From the beginning, Jung was reluctant to embrace many of Freud's theories, yet conversely he was intrigued with Freud and his work. At times Freud and Jung worked closely. Jung was beginning to formulate more of his own theories and had trouble accepting key ideas in Freud's theories. Yet he found himself unable to disagree overtly with Freud as Freud saw him as a loyal protégé. The final break between the two men occurred with the publication of Jung's book on libido (psychic energy) in 1913.

Jung's work was rejected by many of his friends and colleagues leaving him isolated once again. The next 4 years were wrought with a great deal of distress, mystery, and growth. Some reports indicate that Jung had a psychotic break primarily because he was experiencing visions and emotional turmoil. Through these experiences he began to further understand the workings of his unconscious, which led him further along the path to the idea of the collective unconscious.

He studied his dreams and fantasies, drew pictures of his visions, and began to create mandalas (circular drawings that become central to his theory of individuation). This creative and very dark period gave him material to sort through and define for the rest of his life. He did not understand all that was occurring; only that it was significant, and later the meaning would be revealed.

From 1918 to 1919 Jung came out of his so-called darkness. He attributed the change to ending a relationship with a woman who continued to believe his fantasies were inspired by his art. He adamantly opposed this assertion. Some writers point to the curious nature of his insistence on this matter. For when he was a young boy he derived great pleasure, and felt successful, making art. The second factor that released him from his darkness was his understanding of the mandalas he created. Jung found them to be a way of journaling his internal growth.

Jung continued on this journey of understanding the psyche, especially that of the collective unconscious. He traveled throughout the world, which gave him greater evidence for his belief in the collective unconscious and the role of archetypes. Everywhere he visited he was able to see connections to the archetypal and mythical world. The common images existed despite cultural, language, or age barriers.

Jung spent the majority of his life writing about these experiences as well as maintaining an esteemed clinical practice. Jung married in 1903 and had five children. Jung's wife, Emma, also an analyst, contributed to the work of analytic psychology and wrote several works. At the time of his death in 1961 he had 19 grandchildren.

Most of his life Jung was frequently sought after by students and deeply respected. He received many awards throughout the world. He contributed enormously to the field of psychology and continues to have a great number of followers with Jungian analytic institutes worldwide.

Model of the Mind

Jung's theory of the mind rests on the concept of opposites and opposite forces, which is important to be mindful of as his theory unfolds. This section provides an overview of several key concepts of Jungian psychology, including the ego, consciousness, personal unconscious, collective unconscious, individuation, and wholeness. Whenever possible, the implication to the creative process associated with the corresponding structure of the psyche will be made. Psyche, or psychic material, refers to the entirety of both conscious and unconscious psychological processes. The psyche is very complex and works to keep itself in balance.

The Conscious Mind

The conscious part of the mind has the primary job of sustaining the relationship with the ego. The ego is a complex (see autonomous complex in glossary) that contains a great deal of continuity and identity. For psychic material to be conscious, the ego must be aware of the material. Conversely, when psychic material is unknown to the ego, it remains unconscious. Awareness in this case is not merely intellectual but rather intuitive, emotional, and with meaning. Further, consciousness is thought of as the opposite of the unconscious.

The Unconscious Mind

The unconscious is the second psychic structure to which Jung referred. Consciousness is the unconscious' opposite and houses information that is not accessible to the ego but may later be accessible. The unconscious is vast in size and fluid in movement. The relationship, or link, between consciousness and the unconscious is referred to as compensation. Compensation means balancing or adjusting. In this case, compensation comes into play when consciousness is too one-sided, leading the unconscious to try and reach a balance. The personal and the collective are the two substructures of the unconscious. Both substructures serve as a source of art, although in very different ways (which will soon be illustrated).

Personal Unconscious

The personal unconscious, the first layer, is that part of the unconscious specific to the individual. Included in the personal unconscious are repressed memories (memories that have been pushed down into the unconscious without one's control), ideas that are painful, and information without the strength, or the timing, to reach consciousness. Material in the personal unconscious was once conscious and may later be conscious again.

Collective Unconscious

The collective unconscious, the second and deeper layer, is that part of the psyche that is shared by all people, in all cultures, throughout the ages. Jung believed that the collective unconscious is much more important than the personal unconscious because it is the seat of power, wholeness, and internal transformation. The collective unconscious holds dreams, visions, religious experiences, and myths.

He arrived at the idea of the collective unconscious through his knowledge of mythology, anthropology, religion, and art. The collective unconscious concept was further materialized from Jung's work with patients who were diagnosed with schizophrenia (importantly, the collective unconscious is found in everyone, not just in psychotic patients). Furthermore, in his work he realized that images in people's dreams were not from their own personal experience, or life, but rather reminiscent of archaic symbols and images. He began to recognize these images in ancient works and religions that were not in the awareness of the patients who told him their dreams.

In many of Jung's original writings he unknowingly referred to the collective unconscious and the archetypes interchangeably. This confusion has led subsequent authors to speak of the collective unconscious and the archetypes together, not as separate structures. Archetypes are universal structures in the collective unconscious that allow for the potentiality of ideas, but they are not ideas themselves. This point is often a source of confusion and the distinction is important to understand.

Archetypes are revealed by the archetypal image they represent in consciousness. The image is what gives proof of the existence of the archetype. You cannot see an archetype; you can see an archetypal image. Archetypes, and archetypal images, have a strong creative force along with many other qualities. Among the qualities present are favorability, emotion, number, intensity, and type. Archetypes are neither all bad nor all good. Rather, they simply exist, and understanding the importance of the structure is what is key. Intense emotion exudes from archetypal images. Experiences may be within the likeness of all human behavior, but the experiences that manifest within the archetypal category are extraordinarily human; emotional response to an archetypal imagery is enthralling, bigger than life.

Because of the emotional magnitude of the archetypal image it acts as a communication device from the unconscious mind of the individual who produced the work, to the unconscious mind of the individual seeing or reading the work, through the symbolism inherent in the image. The communication is further enhanced by the image relating to mythological figures, or motifs, from ancestry. The manifestations of archetypal images change based on the current culture but are always linked to the past. When an archetypal image is seen or heard or read it evokes a great deal of emotion, power, and release. It is as though the experience is connected to the individual's past and the past of all mankind.

Examples of Archetypes

There are infinite numbers of archetypes and archetypal images. Some of the key archetypes that will be discussed are the anima and the animus, the shadow, the persona, and the self. Other archetypes are the mother, father, warrior, and wise old man, to name a few.

Unconscious archetypes of the opposite sex are referred to as the anima and animus, in Latin these words mean “the soul.” The anima refers to a man’s image of a woman, and animus refers to a woman’s image of a man (which Jung viewed in traditional roles of the 19th century). The anima and animus are thought of as guides, primarily throughout the terrain of the unconscious creating a richer level of understanding of one’s internal world. Another way of thinking about the anima and the animus is in their role of moderating between the conscious ego and the unconscious mind.

The anima was intensely studied by Jung as well as his followers. Less was written by Jung, and his followers, on the concept of the animus. The anima and animus are important for many reasons, especially in relation to the creative process. They are both portrayed continuously in fairy tales, myths, literature, film, and other art forms.

The shadow is another archetypal figure or image. The essence of the shadow is that part of everyone’s personality that is disliked and incongruent with how one would like to be perceived—the part that harbors unacceptable feelings, thoughts, or wishes; distasteful impulses; and negative assessments of oneself. The shadow is actually the part of oneself that an individual can only see sometimes and in varying degrees. Just as the sun creates shadows on all that catches its light, the shadow can be further thought of as the darker, uglier, and evil side of life (e.g., violence, wars, and tragedy, as well as that part of the person who commits such crimes). Further, the shadow is the side of the personality that most people would wish to disown or pretend did not exist. The opposite, or counterpart, to the shadow is the ego. The shadow is often portrayed in movies, books, and art of all kinds.

Persona is the archetype Jung referred to as the mask that everyone wears at times. The persona is thought of as the mediator between the ego and the outside world. The concept of the mask suggests that people respond to the expectations of society by presenting themselves in a certain light, even though the persona is not the true or complete self. In extreme instances, the mask, or persona, is represented in the person who cannot leave his or her professional identity aside. For example, the lawyer is always arguing a point; the preacher is always wearing his or her religious garb and reading from the Bible.

The self archetype is that of wholeness and completion. The self further refers to the ability of the conscious and unconscious to work together in order for an individual to be free to be her or his true self. The integration of all parts of the psyche allows the individual to live in a creative and symbolic fashion—to be truly an individual. The self archetype is the representation of individuation, which will soon be discussed.

Another concept often compared and contrasted to archetypes is the complexes (referred to in the section on consciousness). Jung suggested that there are many complexes in the psyche; unlike the archetypes that number is finite. However, like the archetypes they are neither all bad nor all good; rather they are a part of the psyche to be understood. The autonomy of the complex is possible because the conscious mind does not regulate or control the information. The autonomous complex operates when there is enough energy to move information from the unconscious to consciousness. Even though the information is conscious it is only perceived, not known. The creative complex is one of the autonomous complexes. The autonomous complex is the living part of the creative process, the part that takes on a life of its own (which will be discussed in detail).

Dreams

Jung’s approach to art was similar to his approach to dreams. Jung was inspired by the element of surprise when one awakes, with an uncensored dream. Just as dreams can be puzzling, often the same can be said of art. Dreams can incite further personal inquiry as can some art. The viewer or reader questions art and allows the wondering to pull up unconscious material, just as a dream might.

Individuation

This section provides an overview of the concept of individuation including the concept of wholeness, the integration of mandalas, and the production of active imagination. The process of individuation is key to understanding Jung’s theory of creativity. Individuation further includes the integration of the conscious mind, the personal unconscious, and the collective unconscious.

The cornerstone of Jungian, or analytic, psychology is individuation. The process of individuation, likened to his description of the creative process, is the road of integration between parts of the self that are conflicted. The concept is that opposing parts of the psyche, both conscious and unconscious, are brought into harmony. In addition to the internal work required for individuation is the external work of increasing one’s individuality. Thus, individuation includes both internal and external movement. Full individuation can never be reached; instead Jung believed that it was best to approach it as a lifelong process. Importantly, not everyone chooses or is able to travel down the road of individuation.

The purpose of individuation is to bring about wholeness in the individual. Wholeness suggests that one is able to fulfill one’s destiny and vocation. Wholeness allows the individual to be authentic in the world, thereby avoiding using only the persona, or the mask. Being aware of one’s own internal reality is at issue, not getting rid of a part of the self that is disliked. Coming to terms with the darkness and the painful images in the unconscious is a necessary part of individuation. Also included in the process is greater awareness of the collective unconscious and the collective world around each individual, thus avoiding isolation. A sense of wholeness further encompasses the spiritual aspect of life.

Through the process of individuation, with the hope of reaching wholeness, is the production of archetypal images. These images allow psychic material from the unconscious to become conscious, in varying degrees, thereby freeing difficult material in the collective unconscious. In the case of the artist, moving further along the path of individuation with the production of art subsequently provides the viewer or reader of the art with a similar experience—that of individuation.

One form in which individuation may be expressed is through the making of mandalas, which are a symbol of the psyche's center, or the self. The self, an archetype, is reflective of both conscious and unconscious parts of the psyche. The creation of mandalas was for Jung a tremendous experience of integration within himself, of unconscious and conscious experience. The mandala is a circular drawing usually divided into fourths, or derivations of four or eight. Mandalas are actually used in the East as a form of meditation, although at the time Jung began making them he was not aware of this historical element. He considered this work to be in the realm of religion as opposed to art.

Others have considered the mandala to reside equally within the realm of art. The argument is that a work of art is also an integration of the inner world of the artist and the external world in which the artist lives—again, a representation of the unconscious and the conscious parts of a person.

Another route to individuation is through active imagination, a fantasy activity primarily used by Jung with his patients and with himself. Introspection or meditation is at the center of the activity. Active imagination allows the individual to have a dialogue between consciousness and unconscious. Jung was not certain if the unconscious rules over consciousness or if consciousness rules over the unconscious during active imagination. The key point is the interaction between the two structures of the psyche, the conscious and unconscious, leads to a greater sense of wholeness and individuation.

The form of active imagination can take various shapes such as painting, drawing, writing, and so on. The end result is not what is of primary importance but rather the interplay in the psyche of the creator and the creative process. Jung found that during active imagination, people were able to tap into their unique creative potential. He did not regard this act as making art per se, but rather engaging in their own process of creation.

Artistic Creation

This section provides an overview of Jung's conceptualization of the source and process of creativity, as well as his perception of the artist who creates. Jung was very cautious in his understanding and interpretation of artistic creativity, and he was primarily interested in literature, although he made references to all of the arts. He did not offer a complete theory of art primarily because he wrote on so many other topics, and because of his desire to resist overanalyzing art. As such, he was careful to identify the limits of his psychological study of art activity. In fact, he probably would not have touched the topic if he did not consider making art to be in the realm of psychology.

In general, Jung believed that the process of creation has a feminine quality and the creative work is that of the "mothers," an archetype, within the collective unconscious. As previously stated, much of Jung's theory emphasizes the role of obtaining balance regarding the opposite poles within the individual. The making of art follows through with this idea. When the artist is out of balance psychically, the archetypal image rises to the surface to restore harmony in the individual and, in turn, society, thus aligning with the concept of individuation.

Jung made a distinction between the artist and the actual work of art. Artwork may provide inklings to the artist's life but not reveal the unique qualities of the person who created it. Just as the artist's life may provide clues to understanding the work but not shed light on the meaning entirely, Jung felt strongly that psychology can never fully understand the causality of any work of art largely because the creative urge originates in the unconscious. A reductionist approach to understanding art was contrary to Jung's position. (A reductionist approach to art is attempting to trace all the elements of a work of art to the artist's past.) He was in favor of experiencing a work of art (poetry, paintings, literature, etc.) on its own terms instead of looking for the psychological reasons, or causes, of art. Even though the material of the work can be linked, or traced, to the artist's past, this does not allow others to then understand the actual meaning of the work. In this way, Jung saw the artist as quite separate from her or his creative work. In other words, a work of art in some cases transcends the person and is thus a separate entity. Jung was primarily interested in this type of work, later referred to as type two, or visionary, work.

Types of Artwork

Work that transcends the artist and work that does not was further described by Jung in the following typology. He identified two types of art: one derived from the conscious mind and the second from the unconscious mind. The first type of art is controlled, conscious, and made with a specific intention. Jung later referred to this type of literature as psychological in nature. Psychological, in this case, refers to work that is derived from consciousness such as stories of love, family, crime, and society. These works are easily understood. Artwork of this type, whether literature or painting, is deliberate in that the artist knows exactly what he or she is intending to create. The artist and the creation are one; there are no surprises.

In contrast, the second type of art is unconscious, is uncontrolled, and amazes the artist. The work produced takes on its own form and structure. This type was described as Visionary which does not exclude the psychological quality; rather it goes beyond the personal psychology into the suprapersonal realm. Visionary works are unfamiliar, strange, gigantic, and superhuman.

These works speak to the depths of the human psyche and the beginnings of human existence, holding ideas that transcend the words or images set forth. They are symbols of something unknown. Darkness surrounds them. Visionary works are primordial, or archetypal, experiences rather than personal experiences. The origins of the creative process are the primordial experiences, but the mythological figures give the work conformation. The primordial images, or archetypal images, are dark (e.g., demons and spirits). The mythical figures bring lightness to the dark by appearing less frightful or intense thus bringing harmony to the imagery in a way that is digestible for the current times.

These works are extremely important because they originate in the collective unconscious and bring a message for future generations. Positive or negative, the message is ultimately of value. The artist who produces the second type of work is astonished almost to the point of disbelief. In this experience the artist feels as if someone else has created the work. He or she must allow the process to occur, but not in his or her control. The artist is the vehicle in which the creative process transcends. The artist and the creative process are separate; there are always surprises.

A further distinction is made between the first and second type of artist. The distinction rests on the type of activity set forth by the artist. The first type of creative activity is thought to be introverted and sentimental. Here, Jung borrowed from the work of Johann Schiller in his conceptualization of sentimental and naive. Introverted refers to Jung's idea that the artist consciously shapes and controls the artwork. On the other hand, the second type of creative activity is extraverted and naive. Extraverted refers to the idea that the artist allows the work to control him or her. In other words, the artist's unconscious takes over.

The action of the unconscious is thought to be the creative urge or impulse that may, in a sense, take over the person. The creative urge arises out of the psyche and is extremely powerful. At times, the urge is so strong that everyday life goes by the wayside in order to create. The creative urge is different for all people and varies depending on the type of work produced. The ability to understand both types of work is also different. The first type of work is intentional and comprehensible. The second type of work goes beyond understanding to the same degree that occurred while the artist was in the process of creating it. The image, the poem, or the story can only be understood through intuition and always provides multiple meanings. However, within one piece of work there can be both types of expression.

Further, the second type of art produces a symbol or symbols. A symbol is an expression of an idea that cannot yet be discussed or stated in another, clearer way.

Works that are symbolic are challenging and stimulate the viewer or reader's thoughts and feelings. In contrast, the first type of creative work tends to be more appealing because it is complete, compared to the second type of work.

Symbols are produced for the culture and the spirit, according to Jung. They are a product of the collective unconscious. They are based on intuition and are never planned. Symbols allow society and the individual to move energy from the psyche into valuable accomplishments found in art and science, among other disciplines. Examples of symbolic, or visionary, art are found in the work of Paul Klee, Wassily Kandinsky, Carlo Carra, and Piet Mondrian. These artists were led by visionary images of their inner world that were indescribable.

The inner world is secretive, even to the artists themselves. These artists brought art making to a new level, that of the mystical and the spiritual, though not of a religious order. The manifestation of the spiritual and mystical visions was found in paintings, collages, and unusual figures made from stone, wood, metal, and glass. The tracing of these prominent artists reaches to the time of pagan religions. A very dark nature permeated and was pushed into the unconscious psyche of humankind. Pushing away the darkness created more ugliness and evilness manifested in the form of obsessions, addictions, and so on. Artwork of the beginning of the 20th century (e.g., Kandinsky, Klee, Carra, and Mondrian) brought about a positive resurgence of the primordial spirit in the form of archetypal images.

The part of the unconscious where art originates was important to Jung. He believed that art derived from one's personal unconscious was more a symptom of a problem or situation rather than a symbol manifested from one's collective unconscious. Conversely, art—great art—that is produced from the collective unconscious, or with archetypal images, has a tremendous effect on the viewer. The viewer or reader's collective unconscious is stirred up through the form and shape of the artist's work. In this way, art continues to revitalize connections to the past in a way that is understood by today's culture. Jung believed that this effect revealed the social significance of art and held the artist in high regard. Thus, the creative process is the artists' abilities to manifest archetypal images from the depths of their collective unconscious which is essential for the process of individuation to take place.

In this way the creation of art is what Jung referred to as participation mystique, which is the mystique, or veil, of great art. This movement is in the realm of the collective unconscious. Asking an artist to explain his or her work is unnecessary (largely because great art is beyond explanation), and learning of her or his life is inconsequential and nonexplanatory to the creation. However, he did write the following brief summary about attributes of the artist.

The Artist

Jung saw the artist as an extraordinary human being who is granted the benefit and the tragedy of creative vision. Those who create only, or primarily, from their personal experiences are not in this category. They are expressing a symptom of their experience, as referred to earlier. In contrast, artists who are producing great art must transcend the personal and move into the realm of the collective unconscious, thereby speaking to the mind and heart of humankind. Jung saw the artist as a medium for producing work that speaks for all. He or she does not have conscious control to create or not create but rather is propelled by the collective force to create. The artist does not have a choice.

Not only is the artist a creator but also a human being with wants and desires for everyday happiness and experiences. Jung saw the artist as wrought with conflict because these opposing forces—existence as a human being and as an artist—are not reconciled. Primarily the creator who does not acquiesce to the divine power of creativity that has been granted to him or her will be quite conflicted. The creative force is so strong that there is little energy to do much more in life, namely, the simple pleasures of the average person. The artist is laced with a burdensome existence, often resulting in a selfish, helpless, infantile, and egotistical way of being in the world.

The following analysis of Picasso serves as one, if not the only, analysis of visual art written by Jung.

Picasso

Jung reluctantly and briefly approached the subject of Picasso's artwork, and stayed close to the psychology of his art rather than critiquing his art from an aesthetic point of view. At first he comments on the unfairness of Picasso's work on the viewer, at first viewing these paintings negatively. But eventually the viewer comes to a realization about the world in which these paintings live, an other world. He began to conceptualize this as an entree into the unconscious, which he considered to be dark. He views the images as violent or frightening for some—the opposite of beauty.

Jung's approach followed a chronological history of Picasso's work. Overall, Jung described Picasso's work as nonobjective art, originating from inside, or from his unconscious (earlier referred to as type two artwork). There were a few exceptions, as will be illustrated. Again, work from consciousness, or outer experiences, produces images that are recognizable. The objects may be distorted but not to the degree that they are incomprehensible. Artwork created from the inside takes on a symbolic form, often producing works that are strange, unusual, and not understandable.

Jung viewed four periods of Picasso's work from the blue period to the post-Harlequin period. Picasso's blue period was described as objective, from consciousness. Jung was reportedly concerned with this blue period given the darkness of the midnight blue period which reflected a turn to night. He interpreted the figures in this work as resembling those in the Egyptian underworld. He then moved into a different period, which Jung described as moving into the unconscious, the inside. This period is very dark, characterizing the ugliness and evilness of life. Picasso's work then changed into another form and shape that of the Harlequin, a tragic and ancient god—a very primitive image. The Harlequin image was disturbing to Jung. The period that followed was Picasso's unconscious attempt at conquering his internal conflict—that of opposing forces. The use of piercing, relentless color reflects the strength of the unconscious to handle conflicts of violence.

Summary

Carl Gustav Jung provided a wealth of information to the field of psychology and the process of creativity. From his early days he was ever present to the subtle nuances of the world in which he lived. He was keenly able to integrate his own experiences with those of people around him, from his biological family, to his clients, to his created family. From the beginning he was astonished, amazed, and excited by the duality of life—the secrets of a world of opposites.

This dualism continued to plague and interest him for the duration of his life, and through his own experiences, both internal and external, he developed a complex theory of the human mind. Certainly his theory of the unconscious, with the division of the personal and the collective, was one of his greatest achievements. He has provided a legacy of imaginative, challenging, and intriguing ways of looking at oneself, especially in the creative process.

In his work, Jung provided a theoretical structure of two types of art. The first type is conscious, controlled, and within the realm of the personal. The second type is without limits and truly the work of the collective unconscious, or the archetypes. The second type of art was the focus of Jung's interest because it is the work of the primordial. The images that arise from the collective unconscious are symbolic. Symbolic images are the magical images that the viewer relates to with great emotion although not really understanding why. It is through this process that Jung's theory of individuation comes into play, both for the artist and for the viewer or reader. Again, bringing into play archetypes in the collective unconscious, giving them a voice, and allowing others to experience the transcendence into their own collective unconscious are the stuff of great art.

Jung held great regard for the artist. He believed that the artist was chosen, that the artist did not choose to become a creative agent. The artist's life was wrought with conflict over the unbearable creative urge, on the one hand, and the desire to live an everyday life, on the other hand. Jung believed the artist was a true visionary.

In closing, Jung believed that the creative process was central to having a sense of wholeness within oneself. The sense of wholeness provides the individual with an ability to be a true individual. The process of individuation is achieved through a number of different means with the end result, which is never wholly attainable, being that of an increased sense of self.

Introduction

The role of knowledge in creative thought has been examined extensively in the study of creativity. Although intuitively it may seem that greater knowledge would lead to higher quality ideas, the unique demands that creativity poses make the relationship between knowledge and creativity less straightforward. While knowledge contributes ideas and information relevant to solving ill-defined problems, creativity further requires a restructuring of this information and the integration of new concepts to generate novel and elegant solutions. An overreliance on knowledge in one domain may impede the deviation from previous ideas, constraining focus on what is known rather than what new information could be utilized to develop novel pathways to solving complex problems.

Accordingly, this entry will discuss the role of knowledge in creative thought and discuss recent research streams that shed light on the complex relationship between knowledge and creativity. After first defining knowledge, the available evidence from the literature as it relates to the interplay of knowledge and creativity will be discussed. Finally, considerations for knowledge management will be reviewed.

Knowledge

Knowledge, broadly, is a set of mental structures that are used to both organize and store learned information. Different types of knowledge are organized into different domains, which then are organized into schemas. Schemas are conceptualized as cognitive

structures that consist of linkages among concepts within a domain. Ideally for creativity, domains would be both 1) highly complex with multiple schemas and multiple attributes with many linkages across concepts, and 2) highly flexible, meaning that new schemas and linkages can be created to create novel and unique ways to combine concepts.

The structuring and organization of knowledge is a key component when understanding the link between creativity and knowledge because they provide a framework for how concepts may relate or may be able to be combined to form original and high-quality ideas. Discussion about knowledge and its relation to creativity pertains to whether and how experts, people with high levels of domain-specific knowledge, differ in their creative performance with novices, those who have lower levels of expertise or knowledge in a given domain. Answers to such questions reveal that the benefit of knowledge for creativity is contingent upon the types of knowledge involved and how they are used. To understand how and when knowledge can hinder or benefit creativity, it is first important to the types of knowledge that contribute to creativity.

Types of Knowledge

There are a number of taxonomies representing the different types of knowledge, differentiated by their basic units, organizing principles, and use. The role of knowledge more broadly across creativity research will be discussed in terms of its competing counterparts: depth and breadth of knowledge as well as content and operations.

Depth Versus Breadth

A key feature of knowledge is its domain specificity; knowledge or expertise learned in one content domain is not easily transferrable to other domains. Consider the differences in content across languages. The knowledge that one has regarding vocabulary and the rules of grammar and sentence structure in one language, such as Italian, does not transfer to knowledge of a different language, such as Mandarin. This also applies to knowledge of the sciences or broader industry knowledge.

Studies of the relationship between depth and breadth of knowledge to creativity resulted in mixed findings. Knowledge depth can be conceptualized as extant knowledge in one domain, consisting of more concepts and complex linkages within and across schemas (Mannucci and Yong, 2018). In contrast, breadth refers to knowledge in multiple domains. Scholars have set out to investigate whether depth or breadth of knowledge is more beneficial to creativity. A depth of knowledge could contribute a greater complexity of schemas within a domain with many linkages across concepts. However, knowledge across domains could provide mental linkages across concepts from different domains rather than constraining cognition to linkages across concepts within a domain.

In some studies, evidence was found that individuals with a depth of knowledge generated more novel ideas through the utilization of their complex schemas within a domain. In other studies, individuals with a depth of knowledge became cognitively entrenched so that individuals were unable to deviate from current linkages between concepts. Here, knowledge constrained individuals from being able to form new and original linkages and this hindered their ability to be creative. However, large amounts of knowledge across domains can also lead to information overload, which impairs an individual's ability to sift through these different domains of knowledge and pull only relevant and useful information.

In a study of core crew members who worked in the Hollywood animation industry, scholars attempting to address the question of whether depth or breadth is more beneficial for creativity tested the idea of career age playing an important role (Mannucci and Yong, 2018). The researchers found that the rigidity of knowledge structures was positively related to career age. They also found that the knowledge depth and knowledge breadth are more favorable at different stages across the age of a career. Knowledge depth was found to be more beneficial at early career stages of a career with knowledge breadth found to be more beneficial in later career stages. Overall, this study showed the importance of knowledge complexity, as well as the pitfalls of rigid reliance on knowledge. The authors suggested a restructuring of knowledge across time will aide in stabilizing creative performance. The consideration of time on many phenomena is an important step in investigating the relationship between knowledge and creativity more broadly.

Content Versus Operations

Content

Content refers to the types of knowledge, which can range from industry and task knowledge to more taxonomic types of knowledge, such as schematic and associational knowledge. Researchers have found that the content of knowledge can result in different outcomes for creativity. In a study of 247 undergraduates, researchers investigated the role of content of knowledge (Hunter et al., 2008). Participants were tasked with the generation of solutions for an educational creative problem. Training interventions encouraged the application of different types of content knowledge including associational, schematic, or case-based knowledge. The researchers found that that use of associational knowledge was positively related to the number of ideas generated while the use of schematic or case-based knowledge was positively related to the quality and originality of ideas. Thus, different forms of knowledge content contribute to distinct aspects of creativity.

On the other hand, recent findings also unveiled a link between content and rigidity of thought where the use of associational knowledge can inhibit the production of creative ideas. This can be attributed to the overreliance on existing associations among concepts rather than unique and different connections between concepts across domains. More research is needed to investigate the concurrent use of multiple types of knowledge to further understand these effects.

Operations

In addition to content, operations applied to knowledge also hold significant implications. Operations are thinking strategies that involve combining, elaborating, exploring, and contextualizing content knowledge to form creative solutions. In a study of 155 undergraduates, researchers examined the role of operations of knowledge on creativity (Baughman and Mumford, 1995). Participants were asked to combine concepts from different categories to form novel concepts. The researchers found that the operations of feature search, mapping, and elaboration of ideas contributed to the generation of more highly creative ideas.

Although operations are conceptualized as strategies people use to combine knowledge and form creative ideas, the content of knowledge can also, in return, influence the effectiveness of these cognitive operations. A series of experiments by Ward and colleagues demonstrated this notion, finding evidence that people rely on typical schematic examples of a domain to generate and elaborate upon ideas, even when instructed to be creative. For example, students who were asked to imagine animals on a faraway planet still used familiar attributes of existing animals, such as wings, beaks, or scales (Ward, 1994). Participants who relied less on common examples to generate their ideas showed higher creativity in their drawings and descriptions of new animals and tools. This tendency to rely on familiar examples, however, can be counteracted by combining abstract, rather than concrete, features, or by merging dissimilar, perhaps even opposing, ideas.

Taken together, the strategies that people use to combine information can affect creativity differently depending on the knowledge content. Operations such as feature search, mapping, and elaboration may benefit creativity, but the benefit of these operations may be limited when individuals generate ideas by elaborating from typical examples of a domain. Further, creativity can be fostered by combining abstract or dissimilar ideas instead of concrete or closely related ones. The implications of this research are that the relationships between creativity and knowledge are highly nuanced, and each type of knowledge offers different constraints and benefits to creative outcomes. Accordingly, the following section details specific ways through which knowledge content and operations can hurt or foster creativity.

Knowledge Constraints and Benefits to Creativity

Knowledge as Constraints on Creativity

Constraints from Knowledge Content

One stereotypic assumption about the role of knowledge is that it constrains creativity, most commonly defined as the generation of novel, high quality, and elegant ideas to complex and ill-defined problems. Stemming from research on creativity as divergent and associative thought, this assumption suggests that an overreliance on content knowledge may lead people to recall previous ideas rather than forming new ones (Weisberg, 1999). In this view, researchers argue that creative thought arises from the combination of distally-related information, and dependence on previous, narrowly-focused knowledge may interfere with one's ability to apply new concepts or take different approaches to solve novel and ill-defined problems. Reductions in flexible thinking due to acquired knowledge have often been termed the "cost of expertise" (Sternberg and Frensch, 1992).

To illustrate, in a study of undergraduates solving a social innovation problem, creative thought was inhibited when people were told to apply multiple learned knowledge structures when solving the task (Hunter et al., 2008). Further, a study of 262 benefits broker salespeople that engage in creative selling found that organizational knowledge held a significant negative effect on the relationship between creative selling and sales performance (Groza et al., 2016). It appears that in some cases, learned knowledge can indeed come at a cost to creativity, as it restricts one's capacity to engage in creative thought.

A similar, yet distinct concept to the cost of expertise is the notion of the Beginner's Mind. The Beginner's Mind entails approaching problems with an unassuming and open mindset that is void of preconceived information. Research suggests that expertise can influence the extent to which someone relies discounts new information based on their past knowledge. In a study that examined encoding of information and creativity, researchers found that individuals with higher levels of expertise may falsely assume that previously used information relates to the present problem or discount new information that contradicts their previously learned knowledge (Mumford et al., 2018). This finding confirms past theorizing that knowledge, if tightly embedded in one domain of content, can hinder creativity. Overall, findings suggest that greater domain knowledge and expertise may narrow the breadth of information that an individual applies in creative thought.

Constraints from Operations

A corollary of experts' preference and dependence toward their domain-specific knowledge is their tendency to continue employing knowledge operations that have worked in the past. Experts, then, not only rely on their previous content knowledge to solve novel and ill-defined problems, but they show rigidity in the strategies they employ to innovate. In turn, their persistent use of singular operations can constrain their future creations.

For example, a study of 372 inventors found that inventors who found past success with their innovations were more likely to continue exploiting familiar knowledge to the detriment of future creativity (Audia and Goncalo, 2007). Although successful inventors generated more future patents than less successful inventors, the later inventions of previously successful inventors diverged minimally from their prior ideas. This effect, however, was attenuated when inventors either sought information from others or were encouraged by their companies to explore other domains. The results of this study suggest that continuing to exploit information from the domain in which someone found past success can limit creativity. Yet when the strategy of exploitation is disrupted by external factors that encourage exploration of new knowledge, inventors continued to form divergent ideas. The implication of this

research is that creative success can be found through exploiting a given domain, but continuing to employ the same strategies for later innovations may limit future creativity.

Knowledge as a Benefit to Creativity

Benefits of Knowledge Content

However, other work challenges the cost of expertise and instead supports the notion that creative ideas do depend on one's level of knowledge in a domain. Evidence suggests that, in addition to domain-general creative ability, a person's propensity to generate creative solutions can also benefit from knowledge within a specific domain. Scholars have theorized that the acquisition of knowledge contributes to the repertoire of task-relevant information that people can use to form creative solutions.

Researchers found empirical support for this view in a sample of 187 primary school children (Huang et al., 2017). Students who displayed greater knowledge in mathematics and science demonstrated higher creativity in those domains respectively. Moreover, domain-general divergent thinking ability predicted scientific creativity above and beyond scientific and mathematic achievement, but these effects were not found for mathematic creativity. The results of this study indicate that knowledge contributes to domain-specific creativity in ways that general divergent thinking ability cannot.

Similarly, a study of 183 undergraduate management students found that domain expertise positively related to creative performance on management-related tasks. This finding suggests that creativity within a specific domain benefits from expertise that is relevant to that domain. In other words, expertise ensures that creative solutions appropriately address the problem at hand. The Beginner's Mind, then, may not be useful in situations where people lack the necessary domain knowledge to perform a task.

Benefits of Operations

Evidence also supports a strong positive link between knowledge operations and creative problem solving, where highly creative ideas emerge from individuals who can effectively structure ill-defined problems and evaluate novel solutions. Expertise of knowledge operations enables people to use effective creative problem-solving strategies and avoid ineffective ones. Without adequate knowledge of the operations one could employ in a domain, novices may fail to generate relevant solutions to the task at hand.

In one study on 110 army officers, for example, researchers found that attributes of knowledge structures (i.e., complexity, comprehensiveness, relevance, organization, and diversity) predicted divergent thinking, as well as the generation and implementation of creative solutions (Vincent et al., 2002). Here, distinct applications of expertise were found to improve performance on a number of creativity outcomes, further challenging the view that knowledge hinders creativity.

Another study of 131 young adults compared the evaluative thought and divergent thinking performance of musicians trained in musical improvisation (i.e., a type of knowledge operation), musicians not trained in musical improvisation, and non-musicians (Kleinmintz et al., 2014). The researchers found that musical improvisers tended to rate creative ideas as less deviant or inappropriate than any other group, which led them to produce more original solutions. Knowledge of useful operations thus enables individuals to withhold counterproductive strategies such as evaluating ideas too strictly.

At the core of this view is that individuals with expertise can capitalize and efficiently apply their knowledge to problems at hand. Scholars found that experts can make decisions more quickly, recognize how their knowledge is influenced by context, and can notice smaller details of information than those with less knowledge in a domain (Leonard and Barton, 2014). Several streams of research suggest that, overall, experts make effective and educated decisions surrounding the generation, evaluation, and implementation of ideas. In contrast, novices may lack domain-specific content knowledge and have few problem solving strategies to draw from when generating creative solutions. In sum, expertise may not incur any costs on creativity when it teaches people to think aptly and flexibly within a domain.

The Role of Knowledge Across Operationalizations and Creative Outcomes

Considering the different types of knowledge that individuals possess, and the multiple operations they apply to use that information, it is likely that knowledge affects creativity differently across stages of the creative process. Further, the unique demands and operations required in the creative process may influence the effect of knowledge on different types of creativity. Below is a discussion of the role knowledge plays in various creative operations and outcomes.

Creative Process Stages

Creativity is more adequately conceptualized through process views, where creativity is defined as the result of multiple stages. One common view conceptualizes creativity as a recursive process composed of eight stages, including: (1) problem definition, (2) information gathering, (3) concept selection, (4) conceptual combination, (5) idea generation, (6) idea evaluation, (7) implementation planning, and (8) solution monitoring (Mumford et al., 1991). (See The Four P's of Creativity)

Many studies that examine the relationship between knowledge and creativity explicitly test idea generation or discuss the combination of novel concepts, likened to the conceptual combination stage. In comparison to studies of generative creativity, less attention has been given to the role of knowledge and expertise in other stages of the creative process. Even so, preliminary findings in the realm of idea evaluation suggest that experts are more consistent in their ratings of creativity than novice raters because they have more

knowledge about which ideas are common in a given domain. Overall, more research is needed to investigate the type and level of knowledge as they relate to each creative process stage, as the demands and behaviors at each stage fundamentally differ.

Divergent Thinking Versus Creative Performance

The competing findings on knowledge's relationship with creativity could also be explained by examining how the outcome variable of creativity is operationalized. In some studies, creativity is operationalized as divergent thinking, often consisting of the dimensions of fluency, flexibility, and originality. Other studies examine creative performance, often consisting of the dimensions of appropriateness, originality, and quality.

To address this divide, researchers conducted a study with 143 university students to determine how domain knowledge, among other variables (e.g., general intelligence), predicted creativity as either divergent thinking or creative expert performance (An et al., 2016). The researchers found that while domain knowledge predicted creativity as expert performance, general intelligence predicted performance on a divergent thinking task. Therefore, understanding the effects of knowledge on creativity requires specification about which creative outcome is measured.

Radical Versus Incremental Creativity

Creativity can also be dichotomized as either radical or incremental creativity. Radically creative outcomes are categorized by their exceptional novelty and often paradigm-shifting characteristics. Radical creativity, especially, warrants a strong deviation from previous knowledge, solutions, and thinking in a given domain, often arising from the combination of highly dissimilar information. In contrast, incremental creativity is heavily rooted in previous knowledge in a domain, adding slight novel improvements to existing solutions and ideas over time. The combination of highly distinct knowledge required for radical creativity implies that a strong reliance on domain-specific knowledge may be more detrimental to the generation of radically creative ideas than to the generation of incrementally creative ones. However, it must be noted that expertise still remains a necessary condition for radical innovations in a specific domain.

Team Knowledge

Individual Versus Team Knowledge

Research indicated that when solving a problem, the relevance of information contributed more to the demands of creative thinking than the amount of information. However, to restructure concepts into novel and unique combinations, a diverse set of knowledge is needed and interdisciplinary teams can capitalize on the benefits of both breadth and depth of knowledge. Although individual in-depth expertise has been found to support creative thought, a team of individuals with in-depth expertise in a variety of domains provides a wider and more diverse range of concepts able to be utilized in the generation of creative ideas.

However, researchers recognize that team creative performance is not simply an additive model of individual creativity. Team members need to be both willing and able to effectively share information and knowledge for there to be a positive effect on creative performance. Therefore, teams bring unique challenges centered on group dynamics in the application of knowledge to creative problem solving. (See Teams)

Team Knowledge Sharing

There is limited research on knowledge acquisition in creativity. Above, expertise was discussed in terms of how individuals rely on their own learned knowledge in a domain. However, while working on a collaborative task, individuals can learn from team members as they engage in the creative process and apply new knowledge as a result of knowledge sharing, which has been found to be an important factor for creativity in teams. Additionally, knowledge sharing with members outside of immediate teams can aid in the production of novel and high-quality ideas. For example, biomedical engineers working on a new medical device may need to consult with medical professionals who would eventually be implementing the device in the field. The extent to which individuals can go outside their teams, termed organizational integration and extension, was identified as one of the five core dimensions of an environment that fosters creativity in an effort to establish the core dimensions underlying a creative climate (Heinen, 2018).

Facilitators of Knowledge Sharing

In a study of 350 employees from manufacturing and non-manufacturing organizations, researchers found that leaders foster employee creativity through the facilitation of knowledge sharing between organizational members as well as between their organization and outside members (Carmeli et al., 2013). A study of 198 physicians, psychologists, physiotherapists, nurses, and other healthcare operators examined the role of social capital on the relationship between knowledge sharing and innovative behavior. Findings not only showed a positive effect of knowledge sharing on innovativeness, but also that social capital moderated this effect. Strong ties with others may influence individuals to critically evaluate creative ideas less often resulting in conformity to prevent damage to social bonds (Mura et al., 2013). (See Innovation)

Work on team knowledge sourcing can further delineate how teams can capitalize on and share their collective knowledge. Team knowledge sourcing can be defined as the process of searching for, accessing, transferring, and applying knowledge from each team member as well as knowledge from others outside of the team. This process involves the integration of this sourced knowledge to better understand the problem at hand from the multiple viewpoints available or to combine concepts to form novel solutions that relied on more than one team member's expertise.

Team Knowledge Management

Leaders should emphasize and encourage knowledge sharing with internal team members as well as external sources for effective engagement in cognitive processes associated with creative performance. Additionally, with teamwork comes additional determinants that must be managed for creative performance within teams: team composition, cohesion, norms, groupthink, in-groups and out-groups, risk-taking, and psychological safety (Leonard and Barton, 2014). Leaders should enact practices that capitalize on diversity of knowledge through brainstorming, team knowledge sourcing practices, and the formation of a psychologically safe climate so that team members feel safe to challenge ideas, suggest novel and risky ideas, and to fail without punishment.

Conclusion

This entry summarized research investigating the relationship between knowledge and creativity resulting in two broad conclusions. First, knowledge is essential for generating and evaluating creative ideas. A broad collection of knowledge facilitates the generation of novel ideas because it allows individuals to combine and reorganize distinct information to generate new knowledge. Expertise in a domain also helps individuals understand the relevant context, enabling them to form appropriate ideas and better assess whether certain ideas are truly creative or have been done before. Second, at both the individual and team levels, the relationship between knowledge and creativity depends not only on the type of knowledge available, but also on how it is used. Specifically, knowledge can inhibit creativity when individuals focus too narrowly on familiar information or schemas in one domain. Acquiring and sharing diverse information can counteract the negative effects of knowledge-specificity, and basing ideas on atypical examples of a domain, or combining dissimilar, perhaps even opposing, concepts can result in higher creativity. Thus, when seeking to create, people must consider the types of knowledge they can access and how to use them to best achieve the desired creative outcome.

Glossary

Copyright The exclusive right to make a copy of an original or unique work. The entity owning the right may assign it to another.

Creativity The capacity to make new arrangements of thoughts or matter that are original and useful.

Crowdfunding The funding of a creative project by attracting small financial contributions from many people, typically through an internet campaign.

Intellectual Property (IP) A broad term used to describe the products of creative or inventive activity. The use of the term was rare up to c.1980.

Jurisdiction The right or power to administer justice or to enforce laws

Law The rules governing human relations and behaviors; the control enforced by these rules

Limited liability A form of incorporation that restricts the financial liability of any investor (for a company's debts) to the original value of the shares they own

Patent A document that publicly declares the exclusive right of an individual or other entity to exploit an invention (and gain the economic benefit from it). The term derives from the open letter or 'letters patent' issued by a monarch or other authority.

Power The ability to take an action; the ability to force others to act or prevent them from acting

Property Anything that belongs to some individual, group or other entity

Trademark The (registered) words, symbol, sound, smell or color that, in the mind of the public, uniquely identify the source or manufacturer of a particular product or service.

Creative Acts

Creativity may appear in virtually anything, anywhere: in the design of furniture, modes of transport, farming, architecture, clothing, entertainment, communication or humor. A casual witticism among friends and the development of a new technology are both creative acts, but each makes different demands on learning or material resources. The plan for a great public building may be sketched with pen and paper but its construction depends on the infrastructure of a thriving, stable economy, controlled and directed by laws. The greater the degree to which creative acts engage with the material world the more likely are they to encounter the laws of that world: either its natural or human-made ones. A creative idea that exists only in private thoughts is unlikely to be the subject of legal sanction or influence. The interaction between law and creativity therefore represents the interaction between society's rules and some manifest form of creative expression.

Collaborative large scale projects, like engineering or complex technological tasks, demand educated or skilled people and access to considerable material resources. In contrast, a people living in extreme poverty tend to express their creativity in the less material forms of poetry, music or storytelling. We assume three broad conditions for a creative act: the motivation to solve a problem, the inspiration or information needed to devise possible solutions, and the necessary time, expertise and resources to prototype and perfect a solution.

There is no guarantee that inventive capability will work to order. Greek and Roman civilisations understood the power of steam, but found a use for it merely to manipulate large temple doors. It was not until the industrial age of the 18th century that the right combination of technology and economic purpose found compelling applications for steam power: as pumps to extract groundwater from deep coal mines and as engines pulling coal to the smelting works and factories. The more diverse and energetic the pool of ideas on which society draws the more likely it is to find such applications for our creativity. Institutions and law play a part in supporting the conditions and resources for creative enterprise.

Law and Power

law ... constitutes an integral part of the world power process

McDougal (1952)

Power, in its most appropriate signification, therefore, means security for the conformity between the will of one man and the acts of other men.

Mill (1829)

One definition of a law is "a rule of conduct laid down by a controlling authority", which might mean a body constitutionally recognised (e.g. a state government) or one simply having the power to enforce its rules on a community, with or without the explicit consent of the members. To be effective the authority must have the capacity to enforce the laws. Citizens of a state where certain behaviors are accepted may ignore the laws of a state where they are forbidden, unless they place themselves under that state's jurisdiction. The sanctions of law are usually applied on a scale from a trivial fine to deprivation of liberty—or even life. It is important to note that law is not synonymous with morality, equity or fairness. Many nations had laws upholding slavery as a legal condition and, in the present era, some states retain laws that deny women or ethnic minorities equal treatment in education, work and travel.

Laws May Support or Constrain Creative Expression

The ways in which people may express their creativity are made more or less accessible through individual, social, cultural or economic factors. Those factors, in turn, are shaped by the laws of the community, which may allow greater or lesser freedom of expression, and equality in distribution of opportunities and support. For example, laws like the First Amendment to the United States Constitution were designed to safeguard 'freedom of speech' and have been used to protect the ability to carry out creative acts.

Apart from their effect on creativity laws may themselves be creative, in the sense that legislators may invent an entirely novel rule to solve what they perceive as a social or behavioural problem. Present day democratic governments often present new laws as being for the economic benefit or security of the citizens. Justifications include the welfare of a disadvantaged minority, the maintenance of the environment, the good of future generations, or the observance of the laws of a higher (supernatural) moral authority. While the declared object of any law or sanction may be to benefit the community that benefit may not follow, since a law may be poorly designed or—because of unforeseen consequences—may achieve an object at variance, or even contrary, to the one intended.

Laws are Dynamic Not Fixed

As societies mature, develop technologies and become more complex in operation, the rules are refined. Laws may remain fixed for periods of time but they also change to reflect social and cultural views. They are a product of changing perceptions of the quality

and nature of relations with others. Thus, for example, laws governing property rights, including slavery, have changed substantially over the last 500 years.

Creativity Is Disruptive

It seems a reasonable question to ask why laws should ever oppose the creative impulse; however law is a function of power and authority, and creative acts may be seen as a challenge to those. Webster's Dictionary defines 'creativity' as "the process in which original or meaningful new ideas, forms, interpretations or methods transcend traditional ideas, rules, patterns or relationships" (p. 472). Definitions of creativity point to its necessity to replace tradition, thus drawing attention to its disruptive aspect. The status quo may be strongly defended by those interests most disadvantaged by change. The law's function to maintain the status quo sometimes comes into conflict with the iconoclastic impulse of the creative mind.

Creativity is not always fully accepted, or it may even be discouraged and punished by sanctions of various kinds. In some countries it is forbidden to draw the human form, for instance, because it is an insult to a jealous god.

Dimock (1986: 3)

Among countless historic examples Jacobean playwrights like Ben Jonson were regularly imprisoned for sedition, while Beaumarchais's *Figaro* trilogy and Solzhenitsyn's novels were subject to censorship. Any great art movement, such as Cubism, challenges existing conceptions of art. Change is inevitable, but it is also disruptive to the functioning of the society that supplies the food, shelter and resources to support creative projects.

Censorship

Theatre has often been the object of attack by champions of moral probity, either because it was seen as a distraction from 'honest' work or because of its perceived bawdiness. In England in 1642 the Long Parliament ordered the closure of the theatres, depriving the working population of the opportunity to see the theatrical fruits of the English Renaissance by Jonson, Marlowe, Shakespeare and others. The Licensing Act of 1737 and later Theatre Acts (until 1968) gave the Lord Chamberlain the power of veto, a power the holder of that office exercised as late as 1964 against John Osborne's *A Patriot for Me*.

Laws on what is defined (by those in power) as obscenity lead to the repression of books, artworks and films. In 1920 the US Post Office saw its duty under the 1873 Comstock laws as the seizure and burning of copies of a literary magazine containing episodes of James Joyce's *Ulysses* (a book unavailable for purchase in Joyce's native Ireland until the 1960s). Other reasons advanced for restricting the publication or broadcast of literary or artistic works include the protection of children, counter terrorism, public order, and material deemed offensive to race or religion.

Theocracies—as many nations have been throughout history—tend to impose bans on literature or material deemed contrary to the religious beliefs and principles of the rulers, often imposing severe penalties for a breach of the law. States where church leaders are not in control but have significant influence tend to be restrictive about the range of material the public can access. More recently, internet technologies have had a significant role in circumventing some of these restrictions and allowing greater access to creative works and information.

Education

Apart from direct censorship, laws may affect access to information about the world by enabling or restricting education, limiting the distribution of news or other information and constraining the ability to share information or communicate with others. The social value of open access to information is acknowledged in many ways, including the institution of the public lending library, free schools (like the one that educated library philanthropist Andrew Carnegie), and the 'fair use' exceptions and 'public domain' that are an essential part of the intellectual property system.

Writers and artists play with ideas, improvise and create new arrangements of things they have learned. Inventive acts benefit from technical knowledge, the ability to communicate ideas and to carry them through. These all require an educational infrastructure, laws that bring this into being and make it accessible to the greatest number of people.

For a long period formal educational institutions were reserved for the economically prosperous members of society, or for the religious orders. While the great universities began to appear in Europe in the early medieval period these were essentially seminaries for the sons of wealthy families, teaching philosophy (as theology), classics and mathematics. This began to change throughout the 19th century with the decline of monarchies and the growth of quasi-democratic governments in Europe. As enfranchisement grew in scope so did the need to educate the newly enfranchised, at the same time as technologies produced a demand for a broader curriculum that included the sciences and engineering. Elected governments began to recognise the benefit to the state of increasing literacy and of introducing state sponsored systems of general education. This in turn created opportunities, both in education and career opportunities, for the growing educated (middle) class.

Prussia was one of the first countries—in the second half of the 18th century—to introduce mandatory education for all children between 5 and 13. Defeat by the French early in the Napoleonic wars helped to underline the need for improvement. The policy was copied in other places. In Britain the Education Act of 1870 created local education boards, while Acts in 1880 and 1891 made it mandatory for children under 13 to attend school and introduced free primary education. Control began to move from religious factions to the secular authorities. Similar reforms were introduced in France by Premier Jules Ferry in 1881 and such schemes are now the norm.

Laws providing free education for older children and for young adults (third level) were introduced in different countries at different times. The Education Act of 1962 exempted British residents from university fees (until 1998) and introduced a means-tested maintenance grant. The effect of this may be seen in the fact that while in 1913 there were 13,000 students at British universities (from a population of 36 million), by 2016 this proportion had grown to 2.3 million students in a population of 65 million. Likewise the Danish government, with the aim of ensuring education is not based exclusively on a family's ability to pay, pays fees for its third level students along with a monthly stipend for maintenance.

Free third level education is far from universal. While governments everywhere seem to have accepted the idea that free mandatory education for young children is essential, an ideological disagreement remains on whether the state should pay the costs at more advanced levels. The decision seems to revolve around whether higher education is considered by those in power to be a right or a privilege, and whether the benefit is seen to accrue to the individual or to society at large.

One obvious consequence of the growth of a professional educated class has been the increase in the share of national income—as wages—to those with educational qualifications. This has brought an increase in status and respect for the capability and individual contribution of the educated. This increase in access to resources and time has also been responsible for some remarkable creative contributions to society including (but far from limited to) the development of antibiotics, DNA and the technologies of the internet.

Women: Creative Potential Lost

Laws remain in many countries that discriminate against women in terms of property ownership, freedom of movement, education and other opportunities. The struggle by women for full self-expression persists in those countries that make it difficult or impossible for them to operate without male approval.

Virginia Woolf's 1929 essay *A Room of One's Own* imagines an alternate reality where Shakespeare's equally gifted sister, Judith, would have been denied even the relatively limited opportunities available to William, including an education. She might have existed in the drudgery of household chores and eventually been forced into an arranged marriage. In Woolf's imagined narrative Judith's attempts to find expression for her creativity by running away and joining an acting troupe meet with ridicule (since women did not act on the Elizabethan stage) and end in tragedy.

Educational opportunities for women lagged severely behind men. Despite its educational reforms, the Prussian system paid little attention to its separate girls schools or curriculum (Albisetti, 1985), while the United Kingdom had few schools for girls in the 1860s. It was not until near the end of the 19th century that the universities began to open their doors to women students, often in women-only colleges like Girton in Cambridge. The legacy of this unequal distribution of opportunity persists in the record of invention. An examination of United States Patent Office (USPTO) patents from 1994 to 2003 reveals that the proportion granted to individual female inventors may be no more than 5 per cent, indicating an unrealized potential for creativity.

Access to News and Information

It is imperative to have accurate and timely information about the state of the world and current events to inform judgments and actions. For this reason those who wish to mislead the public usually begin the process by hiding or distorting key information. Hence propaganda or 'spin' is frowned on as being the means of manipulating people to approve some faction's desired programme.

The pace of personal communication has quickened, through technologies including signalling, telegraph, and telecommunications. The most recent technology, the internet—particularly when paired with a browser and email equipped 'smartphone'—has been very successful in permitting open communication and relatively free dissemination of information between individuals anywhere on the planet. This has posed a new challenge to authoritarian governments that traditionally suppressed their population's access to information about the world. In some cases the sheer poverty of a country has denied its poorer members access to expensive technologies. Other authoritarian strategies depend on technically blocking access to the Internet, on selection and filtering of content, sites and organisations, and on the deterrence effect of penalties for breach of the laws.

Self-actualization

Maslow's hierarchy of needs often appears in discussions of creativity, usually in the context of our 'peak' need for 'self actualization'—the need to realise potential, including the impulse to create. At the base of Maslow's hierarchy lie fundamental needs: food, shelter and safety that tend to dominate thoughts and actions until they are achieved. Poverty may be a constraint on creative opportunities, since an instability of basic needs diverts attention toward mere survival. Of course even people struggling to maintain the

basics of life still find ways to express their creative impulse. The exquisite Paleolithic cave drawings at places like Lascaux or Altamira suggest that, as soon as the basic necessities of existence have been provided for, people begin to find avenues for personal creative expression, but large scale creative projects require planning, time, experimentation, technical expertise and often great collaborative effort.

Laws that affect status may either enhance the ability to deliver creative projects, or deprive individuals of the autonomy, leisure, and social standing to carry them out. In this category are laws that favor one group over another, or discriminate on the basis of class or ethnicity. For example, the aboriginal population of Australia was denied the vote under the Commonwealth Franchise Act of 1901 “ostensibly because of their limited literacy and command of English” (Cannadine, 2013). Such treatment under the law denies resources and raises barriers against an individual or group’s ability to express themselves.

Class and Social Division

The notion of social order—a natural hierarchy from a monarch down to the lowest class—is embedded in history. This hierarchy was supported by laws to emphasise the distinctions between the classes and their different privileges and obligations. From birth, the lower orders were confined to a narrow range of occupations, most commonly agricultural work. Restrictions aimed at the poor—including laws that tied laborers to their birthplace, punished homelessness, or outlawed vagrancy and begging—denied large numbers of people the opportunity to improve their situation beyond the most basic level of existence.

Debt, Bankruptcy and Financial Penalties

Debt has a dampening effect on innovation. Research shows that the severity of bankruptcy laws significantly affects innovation, as measured by the rate of start-up enterprises (Armour and Cumming, 2008). Bankruptcy declaration is a legal declaration that a debtor is unable to repay their debts and, in more lenient regimes, amounts to a form of debt forgiveness. Those countries with a minimal bankruptcy term prior to discharge (like the United States) enable entrepreneurs to make further attempts at innovation. Armed with the valuable experience of failure people learn to “fail better.” Walt Disney and Henry Ford are among the many beneficiaries of the United States’ lenient bankruptcy terms and limited liability laws.

In a jurisdiction with more severe bankruptcy terms an individual without the financial support of wealthy patrons or family will find the consequences of failure are severe; they will be unlikely to raise sufficient capital for more than a single attempt, or will be permanently deterred from starting any enterprise: “The policy implications are seemingly straightforward: forgiving personal bankruptcy laws and ready access to limited liability offer significant policy instruments for enhancing entrepreneurial activity” (Armour and Cumming, 2008, 337).

Other fixed financial penalties, fines or costs may have very different consequences at different levels of income. Even basic fines may quickly consume the resources of people on lower incomes. As a New York Times article put it: “While a \$250 speeding ticket means little to a millionaire, it’s roughly a week’s pay for someone earning minimum wage” (Schierenbeck, 2018). Likewise, for someone on London’s minimum wage a single parking fine may represent half a week’s income.

Property Rights

The institution of private property rights and the extension of the franchise were important elements in moving from a feudal to an industrial society and a wider distribution of innovative projects. The main argument in favor of private property rights is that they are the most efficient way of exploiting a scarce and valuable resource (land) for the benefit of society, since a property owner is motivated to improve their property through innovation, which ultimately serves the common good. The five personal benefits to the individual of owning large amounts of property were identified by the 15th Earl of Derby in 1881 as political influence, social status, the power to command tenants, rental income and the leisure that income provides (Cahill, 2002: 8). In the past, ownership of property has been a qualification for participation in the political process, one that was abolished in the United Kingdom as recently as 1918.

It is an obvious problem that property is a strictly limited resource and—as populations grow rapidly and wealth aggregates (under heredity laws for example) — the stock of available property is diminishing. Future generations are, on average, less likely to enjoy the benefits of property ownership and—being entirely dependent on wage income—may find themselves in a neo-feudal relationship with a property-owning class (in effect working to pay escalating rent).

Laws may be used to remove some property rights and bring new ones into existence. For example, the ownership of people as property was made illegal in most countries during the 19th and early 20th centuries. In England, from around 1600, a series of Inclosure Acts were used to create property rights for individuals in land previously held by the community in common. In America—in a brief period of thirty years from 1790 to 1820—the indigenous population found that their status as ‘owners’ of the land had been changed to one of ‘occupiers’ in what Banner (2007) describes as a “major change in American legal thought”.

Propertization of Ideas

A surge in the appearance of laws characterizing ideas as a form of property occurred in the 19th century, seemingly as a consequence of the rapid growth of manufacturing industry, as firms better understood that owning inventions and other ‘intangible’ assets could

be highly profitable. The term “intellectual property” (IP) came into vogue around 1980 as a means of attaching the long-established concept of land ownership to the far less clearly defined and often nebulous products of creativity. One important difference is that while real estate is already a scarce good, making property of ideas introduces “a scarcity of the products appropriated which could not otherwise be maintained” (Plant, 1934).

Advocates of the propertization of ideas argue that ensuring the financial benefit to artists and inventors provides an incentive for creative work that the free market fails to provide, proliferates the ideas that lead to progress, and directs capital towards useful projects. Critics of the IP regime argue that a private monopoly on ideas removes opportunities for others to improve on them, blocks some avenues for scientific research, replaces open collaboration with secrecy and antagonistic competition, free-rides on education and research paid for by the public, favors wealthy corporations over individuals and small firms, inflates the costs of essential drugs and important technologies, and proliferates controversial claims of ownership.

The laws governing ideas as property may be broadly separated into the three areas of copyrights, patents and trademarks. The first two of these most concern creativity since they deal with laws that directly protect the right to make copies (of a book, artwork or film for example) and laws that allow inventors to exclude others from using their invention. Trademark registration protects the unique identifying marque or brand of the supplier of a product or service. Unlike real estate, copyright protected works and patented inventions return to the public domain after a fixed term of years.

Copyright

The laws forbidding unauthorized copying evolved to match developments in technologies that facilitate easier reproduction. An illuminated manuscript produced by early Christian or Coptic monks could not, at that time, be reproduced by any means other than the same months of skilled manual work spent in first creating it. With the introduction and improvement of printing technologies after Gutenberg the ability to make copies was greatly enhanced. Digital reproduction is now trivial, and has enabled the almost infinite generation of copies of text, images, film and music.

The presumption of laws to protect against unauthorised copying is that the original creator of a work will not otherwise benefit from the labor involved in creating it. The US Constitution of 1789 explicitly addresses that point: [The Congress shall have power] “To promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries.”

In England the right to print and publish was controlled for 300 years by the guild of Stationers, the craftsmen who produced pamphlets and texts to sell at their ‘stations’ against the walls of St Paul’s Cathedral. The Stationers’ monopoly and the low fees paid to writers did not make the career of professional author attractive; William Shakespeare’s main income came as a shareholder and actor in the theatre company for which he wrote. After the monopoly of the Stationers’ Company came to an end in 1694 the first true public copyright act, the Statute of Anne in 1710, gave authors some control of their manuscripts for a term of 14 years and raised the prospect of authorship as a profession. Most countries still lacked public copyright laws. In France, until 1789, the *droit d’auteur* was a privilege under the King’s patronage, while German copyright law awaited unification in 1871.

The first international agreement on copyright came at Berne in 1886 at a meeting of lawyers representing the major publishing firms (Ricketson, 1987). Copyright duration terms proposed at the meeting ranged from 20 years to perpetuity, but the term finally agreed was the author’s lifetime plus 50 years (extended to 70 years *post mortem* in the 1990s). In a recent trend media companies facing the problem of copyright expiring on valuable assets have begun to claim trademark rights on as much as possible of the content. Since a trademark right persists as long as the owner continues to use it, the Disney or Harry Potter characters, and everything associated with those, are protected for as long as the corporations that own the rights continue in trade.

The ease of distribution for digital files on the internet raised the tempo of the debate about copyright. The main argument is between those who feel that the internet should remain as open and free as possible and those who seek to be compensated for each instance of the publication of their work. Some copyright holders, led by large media groups, are lobbying government to make internet service providers, like Google or YouTube, legally liable for copyright infringement. Requirements like those in Article 13 of the current European Union’s (EU) Copyright Directive may oblige web services to block uploaded material until its ownership can be determined.

It is impossible to predict the consequences of laws tightening control of copyright material. One possibility is that the public—unable to afford the full price of the better known or heavily marketed artists—may turn their attention to up and coming performers, artists and writers prepared to offer their work for minimal payment through net patronage services like Patreon, or through crowdfunding. Strategies like this are increasingly common on the internet where there is a benefit to early career writers and artists in forgoing payment in favor of broad distribution and rapid exposure. Other models for recovering value for creative work have been proposed, including micro payments, taxation and public subsidy.

Inventions and Patents

The patent originated as a privilege granted by a monarch, usually in the form of an open (patent) letter, giving individual subjects the exclusive right to receive the revenue from some novelty in production, industry or technical method. The issuing of *letters patent* became a means of generating revenue for the Crown, and led to their proliferation and abuse, which the English Parliament addressed in the first patent statute, the 1624 Statute of Monopolies. In the United States the clause in the 1789 Constitution giving Congress the power to promote “science and the useful arts”, was intended to provide a similar monopoly and incentive to inventors “for limited times”.

Laws governing the issuing of patent monopolies rapidly appeared in every country. An important part of the logic for issuing the monopoly was the notion of an exchange. The inventor was given the protected right to solely benefit from their invention for some fixed period, in return for adding to public knowledge by clearly explaining and publishing its detail and methods.

As industry and trade increasingly began to cross international borders during the 19th century international agreements on trade and property rights were needed. Key developments were the 1883 Paris Convention for the Protection of Industrial Property and, in 1994, the Trade-Related Aspects of Intellectual Property Rights (TRIPS) agreement as part of the Uruguay Round of GATT talks. The TRIPS agreement obliged developing economies to observe the IP rights of the major established economies as a condition of access to international trade. It was a precursor to a succession of subsequent bilateral agreements and free trade agreements strengthening the power of international corporations.

Out of the 300,000 or more new inventions granted patents each year by the USPTO or the EU only a small proportion contain an important novelty or provide licencing revenue. For most individuals or start-up firms the costs of acquiring a patent (and defending it in the rare case when it is infringed) are a burden on their limited resources. In reality the majority of patents today are granted to large corporations with the resources to manage a large patent portfolio and exploit this in multiple ways: as a defensive barrier, to challenge rival firms in court, as bargaining leverage, to exploit tax schemes and loopholes, or as an entry ticket to a promising technology consortium. A large technology corporation like IBM or Samsung acquires over 8000 patents in a single year, in multiple jurisdictions. In sharp contrast the average small firm may acquire fewer than five patents over the firm's lifetime.

Corporations, Power and the Law

Throughout history the effective power to create or amend law has mainly attached to a specific geographic jurisdiction—a national government being the primary example. During the second half of the 19th century large corporations began to develop the power to influence legislation across national boundaries.

The corporation began as a group of individuals joining together to achieve business or social goals beyond the resources of any one member. An important legal change came in the 19th century with society's gift to the corporation of limited liability. Limiting investor's liability to the nominal value of their shares removed most of their risk and allowed firms to attract the capital for large scale and hugely profitable ventures. Corporations have been able to lobby for and influence further legal changes, national and international, including the 1952 US Patent Act which favored the interests of large pharmaceutical firms, and the already referenced TRIPS agreement. Since power and law are closely associated, the modern corporation, with virtually unlimited financial and legal resources, presents an imposing obstacle and deterrent to the individual or small firm in any case involving intellectual property.

Concluding Remarks

This survey of the relationship between law and creativity touched upon the very broad range of factors where the law, at different times and in different ways, acting on individuals and on the community, may affect the capacity to conceive and accomplish creative projects. History suggests that the spread of learning and wide distribution of information are fundamental to enabling and stimulating creative ideas. A community largely reduced to scavenging for food or shelter will struggle to find the resources to engage in great enterprise. A broad and balanced distribution of opportunities and resources encourages diversity and increases the probability of useful innovation.

Creativity benefits from rules that enable a stable society that meets economic and educational needs for most citizens, provides opportunities and resources, and supports innovation and collaborative enterprise. The rules may also be restrictive by favoring interests, obstructing certain groups or sections of society, or aggregating control of resources to a narrow segment of the population. Laws may thus profoundly affect the capacity for a society to be creative.

Glossary

Leadership The exercise of influence over others either through behaviors or actions.

Followers Those who work for a leader.

Climate People's perceptions of their work environment.

Mission A tasking given to followers by a leader.

Projects An integrated set of work activities intended to produce a product.

Championing Advocating for resources or support needed to work on a project.

Leadership

Many peoples image of creative people is based on a myth. This myth holds that a genius working alone, triumphs over incredible odds to make a creative idea real or produce an innovative product. Although this romantic myth is compelling, it simply does not have much to do with the reality of creative work.

Creative work in the real-world requires substantial resources. Who will provide these resources? Creative ideas often fail, and sometimes succeed. Who evaluates the success or failure of creative efforts? Creative work typically involves a number of people, often very strong-willed people, with very different ideas. Who will get these people to work together? Many approaches might be used to develop an innovative new product, but who will decide what products and approaches are to be pursued?

These questions are all critical for understanding the success of creative efforts in real-world settings. Examples include the development of transistors, power systems, and space flight. More centrally, all these questions point to the need for effective leadership of creative projects. This entry will examine the key activities that must be executed by those asked to lead creative efforts. Then capacities needed by leaders will be examined, as well as the errors they are prone to make. Before turning to these issues, this entry will examine what is meant by the term leadership and the evidence indicating that effective leadership impacts creative performance in real-world settings.

Institutions, organizations, and firms all represent complex social systems where resources and inputs are transformed to produce viable and valued outputs. Although the production of products and services is often seen as an inherently non-creative activity, virtually all institutions, or firms, are initially based on a new, creative, idea. In fact, the survival and/or profitability of institutions, or firms, is often based on their ability to develop new products or services or adapt extant products and services to changing customer needs. Put differently, creativity—the generation of new ideas—provides the basis for sustained innovation or the development of ideas into viable new products and services.

In firms, or institutions, multiple parties are involved in the development and deployment of any new product or service. In addition, substantial resources are typically required over lengthy periods of time to allow for the development and deployment of these new products and services. Thus, it is usually large, rich, firms that produce radical, new, innovative products. Remember, it was Xerox, not Apple, that developed Graphical User Interfaces. In firms, however, decisions must be made as to what ideas are to be pursued and what resources are to be invested in these ideas. Moreover, multiple people and multiple functional units, such as,

[☆] *Change History:* July 2019. Michael Mumford updated the text throughout the article.

This article is an update of M.D. Mumford, J.D. Barrett, Leadership, Editor(s): Mark A. Runco, Steven R. Pritzker, Encyclopedia of Creativity (Second Edition), Academic Press, 2011, Pages 41–46.

research and development, marketing, and production, must be marshalled to generate creative ideas and turn these ideas into viable new products or services. In firms, the coordination of various stakeholders, and decisions about investment of firm resources, are commonly held to be the prerogative of those who occupy leadership roles.

Leadership roles require direction of the activities of multiple people, stakeholder groups, or the firm as a whole. Thus, as noted by Bass and Bass (2009), leadership is critical to the performance of firms, work teams, and people working in these teams. The direction of action implies that those occupying these roles must exercise influence. Thus, leadership is defined as the exercise of influence in a social context, where influence can be exercised either through direct actions, such as the leader's interaction with a person they are responsible for (a follower), or indirect actions, such as setting unit budgets or articulating a vision for the firm.

Leadership and Creative Performance

Because creative people need autonomy, some people assume that leaders, by influencing people, inherently inhibit creativity, and, subsequently, innovation. This assumption, however, is perhaps too simplistic. Creative work also requires resources. It requires collaboration and support from others— and, these observations suggest leadership might be critical to creativity and innovation. In fact, Mumford et al. (2019), note the evidence accrued over the years indicates leadership is crucial to the creativity and innovation in real world settings. Consider a few examples.

Barnowe (1975) examined the productivity of 81 research and developments teams, including some 900 chemists. Team creativity was appraised with respect to publication rate, and leader behavior was appraised by team members in terms of leader support for followers, participation, closeness of supervision, and leader technical skill. It was found that these leader behaviors were correlated, in the 0.40's, with evidence of research productivity.

In another study, Tierney et al. (1999) asked 191 chemists working in a research and development unit to describe how positive their social exchange relationships were with their supervisor or leader. Invention disclosures, production of research reports, and senior managers' appraisals of team creativity were measured. It was found that positive exchange relationships were correlated in the 0.20's with these indices of creative performance.

In still another study, Keller (2006) asked scientists, all engineers working in 181 research and development project teams, drawn from five firms, to appraise transformational behavior by team leaders—behaviors such as idealized motivation, individual consideration and intellectual stimulation. In addition, team members were asked to appraise structuring behavior by leaders. It was found that both, transformational leadership and leader structuring behaviors were strongly related ($r \approx 0.35$) to technical creative work accomplished by these project teams.

Not only is leader behavior strongly positively related to creative production, it is related to a number of other outcomes of creative efforts in the real-world. Effective leadership results in:

- Greater investment in, or motivation for, creative work.
- Greater satisfaction with the work being done.
- Better learning, or growth, from the creative work being done.
- Better objective performance—more patents, better schedule performance, and better budget performance.
- The development and deployment of both more incremental innovative products and more radical innovative products.

When one considers these findings, the general conclusion seems clear – effective leadership is a powerful force contributing to creative achievement in the real-world at an individual, team, unit, and firm level.

Leader Activities

Although many extant models of leadership, for example leader-member exchange and transformational leadership, showed leader behavior contributes to creative achievement, these models all seem to result in ambiguities that limit their value as a vehicle for understanding how leaders influence follower creativity. For example, research indicated that while transformational leadership behavior may motivate creative efforts, transformational behaviors also induce dependence on the leader which may act to undermine creativity. Similarly, although positive leader-member exchange may induce feelings of safety, which allows people to undertake creative work, positive exchange relationship may limit the deep criticisms found to be critical to production of more creative problem solutions. (See Teams)

The ambiguities which arise when general models of leadership are used to account for creativity led Mumford and his colleagues (Robledo et al., 2012) to propose a model of leadership expressly focused on the leadership of creative efforts. This model, presented in Fig. 1, holds that the leaders of creative efforts must engage in three global types of activities. They must lead the work, they must lead the people doing the work, and they must lead the firm.

In a test of this model, Vessey et al. (2014) obtained academic biographies of 93 historically notable scientists and engineers. For example, J. Robert Oppenheimer (Physics), Frederick Taylor (Metallurgy), and William James (Psychology), who over their careers led multiple teams working on a variety of creative projects. Judges were asked to code, based on the material presented in these biographies, the extent to which the leader effectively executed each of the key activities specified in this model. These activities included planning, establishing a creative climate, and acquiring requisite resources. Performance was assessed with respect to objective indices such as awards won, number of creative products produced, and article impact, among other indices. It was found

Figure 1 Tripartite model of the requirements for effective leadership of creative efforts (Robledo et al., 2012). Reprinted with the permission of the authors.

that effective execution of these activities accounted for both professional impact of the leader and, notably, the performance of the teams they led. Although additional validation evidence is needed, these findings suggest that Mumford's model may well account for effective leadership of creative teams.

Leading the Work

Creative work occurs in a socio-technical context, which is in constant flux. This observation has a rather straightforward implication—leaders must be constantly scanning their work environment and gathering information about what is going on, who is doing what, and making sense of the information gathered. In fact, many studies showed the quality and intensity of leader scanning activities were positively related to the success of creative efforts. In this regard, however, two key points should be borne in mind. First, leaders often acquire this information from an extensive, perhaps a bit loose, network of contacts. Second, in scanning, leaders must focus on both the professional field *and* the institutional context in which the work is being conducted. Put somewhat differently, leaders must look both inward, to the firm, and outward to the profession.

Scanning provides leaders with a basis for defining key themes to be pursued in project work. From the perspective of the leader, the value of creative work is learning with respect to these themes and development of new products or processes based on this learning. Learning in firms, however, depends on expertise acquired slowly and with great difficulty. Thus, the themes pursued by leaders are not open, but structured with respect to fundamentals—for example Dupont's progressive work on long chain polymers or AT&T's work on communication efficiency and robustness. Leaders establish projects to explore key emerging themes that might pay off in understanding and exploiting a limited set of fundamentals.

A key requirement imposed on those who lead creative efforts is structuring the work to be conducted—a key activity given the novel, complex, and ill-defined nature of creative problems. Of course, effective structuring of project work requires planning. In keeping with this observation Hemlin (2009) has shown that while leaders of creative efforts will delegate many activities, they do not delegate planning. Marta et al. (2005) have shown that leader planning skills are a crucial determinant of the success of teams working on creative projects.

What should be recognized here is that the plans formulated by the leaders of creative efforts are not rigid action steps, rather leaders must envision the future—how work will be conducted and how it might unfold over time. Plans of this sort allow leaders not only to structure work, they also allow for identification and exploitation of emergent opportunities.

Leader plans, however, provide a basis for two other critical activities. First, plans provide leaders with the basis for defining the specific mission to be given to the people doing the creative work. Missions structure people's work without requiring overly close supervision. Second, plans and missions provide leaders with the basis for providing their followers with feedback concerning the work they have executed. Creative people seek contact with leaders early on when defining the parameters within which they are

working, and when seeking evaluative feedback on the work they completed. Thus, evaluative feedback should be technically appropriate with respect to the mission at hand.

Ongoing evaluation and feedback by leaders requires intimate involvement with the projects being pursued. This active engagement in project work allows leaders to actively monitor project work and help followers resolve the many varied crises that arise in the course of any creative project. This monitoring activity allows leaders to reconfigure projects when necessary and bring projects to fielding and production.

Leading the Group

Leader plans are of particular significance because they provide leaders with a framework for identifying what types of expertise, or what types of people, will be needed for a project to unfold successfully. There is not much empirical research examining how the leaders of creative efforts recruit team members. However, qualitative studies have indicated that recruitment of team members is a crucial responsibility of leaders. What should be recognized here is that leaders cannot simply “tell” a creative person to work on a project. Leaders must “sell” the project’s professional significance for the field and advancement of their career.

Once team members have been recruited, their interactions with each other, the project, and the leader will establish a climate. And, it has long been realized that peoples’ perception of their working environment is one of the most powerful predictors of creative achievement (Hunter et al., 2007). What should be realized here is that climate is largely, although not totally, established by the leader.

This brings up a new question. How should leaders interact with followers to establish a creative team climate? Over the years, many dimensions of the work environment have been held to contribute to creative climate perceptions. For example, a positive peer group, supervisory support, opportunities for participation, and playfulness to name a few. Hunter et al. (2007) conducted a meta-analysis study examining the effects of these climate dimensions on creative performance. Although all the climate dimensions contributed to creative performance, three dimensions exerted especially strong effects: 1) challenging missions, 2) intellectual stimulation, and 3) positive interpersonal exchange.

Thus, leaders of creative efforts must encourage people to actively think about the mission at hand, challenge them intellectually, and encourage people to work together to address these challenges. Of course, given the nature of creative people, this may prove more difficult than it might appear. Thus, leaders may use a variety of tactics to establish such an environment. They may encourage all to contribute in project meetings. They may ask team members to present anticipated next steps for team review. They may encourage public dissemination of project work with all contributors being listed as authors.

Establishing a creative climate is of value for another reason, it provides a context for positive leader-follower interactions. Positive leader-follower interactions allow followers to feel safe in their work and trust both the leader and other colleagues. Positive interactions, however, are not simply a matter of the leader being pleasant. Rather, leaders must help creative people do their work and respect the value of the work that they are doing. Thus, leaders must serve not only as a mentor, but as a senior technical advisor and sounding board for followers as well.

Leading the Organization

Leader plans are not only central to leading the work and recruiting followers. They are also central to obtaining the resources required to pursue creative projects. The available evidence indicates that top management support for creative projects, support providing adequate, sustained, resources and establishing the legitimacy of the creative effort, is a critical determinant of project survival and success. It is the leaders of creative efforts who must recruit this support from top management. In other words, leaders must sell, or champion, the creative efforts they envisioned.

Howell and Boies (2004) examined what leaders need to do in order to champion their projects to institutions. They obtained 19 pairs of matched product champions and non-champions working in information technology firms fielding 28 new products. These champions were interviewed, and interview transcripts were content coded. It was found that product champions both packaged ideas and sold those ideas. Effective packaging and sale were found to depend on normative knowledge, or understanding of the firm’s business process, and contextual knowledge, or understanding of the firm’s business strategy. In other words, leaders of creative efforts must know the firm, and its strategy, in order to sell ideas and acquire requisite resources.

Leaders, however, must do more than attempt to garner top management support. They must also build support among other key stakeholders in the firm—new projects must be built (manufacturing) and sold (marketing). Notably, if key stakeholders do not support an effort, even if top management does, it will fail. Moreover, at certain points as projects unfold, staff must be recruited from, and infused into, creative teams. Although such cross-functional teaming arrangements are known to contribute to the success of new project development efforts, cross-functional teaming is unlikely to occur if relevant institutional stakeholders will not support the creative effort.

These observations are noteworthy because they imply that leaders of creative efforts must do four things. First, the leader must build personal connections to key people in each stakeholder group. Second, they must understand the implications of the creative effort for routine operations in the stakeholder group. Third, they must educate the stakeholder group as to the implications of the creative effort. Fourth, they must help the stakeholder groups address problems raised for them by the creative effort. Thus, those asked to lead creative efforts must also become teachers.

What should be realized here is that such instructional activities provide leaders with an understanding of who in different functional units has expertise that might prove of value to creative teams. Thus, such actions provide a basis for importing expertise into creative teams. By the same token, the reactions of creative teams to these “imports” may not be positive—they come from different fields, have only a limited history with the project, and often will not know project staff. Thus, leaders

must clearly articulate to team members why new staff have been brought aboard and how they will be expected to contribute to project work.

Leading Capacities

When one looks at the key activities required of those asked to lead creative efforts a new question comes to fore. What capacities must leaders possess to execute those varied activities effectively? One key capacity is implied by the need for leaders to plan creative projects and provide people with feedback concerning their creative work. The leaders of creative efforts must themselves possess substantial creative thinking skills. In fact, [Zaccaro et al. \(2015\)](#) showed that the extent to which leaders possess creative thinking skills, problem definition, conceptual combination, and idea generation skills, was a crucial determinant of both leader and team performance when working on tasks requiring creative problem solutions.

Along with creative thinking skills, however, leaders of creative efforts must have substantial planning skills. In fact, the [Marta et al. \(2005\)](#) study indicated that planning skills may be critical to effective leadership of creative efforts. In this study, teams were asked to formulate plans for turning around a failing automotive company. These plans were appraised for quality, originality, and elegance. Team members nominated leaders and all participants were appraised with respect to planning skills and structuring behavior. The most creative solutions were obtained when team leaders evidenced strong planning skills in part because these skills contributed to better task structuring.

The importance of planning skills points to another capacity that must be possessed by those asked to lead creative efforts. The kinds of plans one formulates in one domain are different than those needed in other domains. Thus, it is reasonable to assume that those asked to lead creative efforts must possess substantial expertise. In fact, prior studies showed that creative people will not accept influence attempts unless the influence attempt is expertise based. In other words, influence must be exercised with respect to the work to be done. Not only do the leaders of creative efforts need substantial technical expertise, they must also have expertise with regard to the organization, and its operations, if they are to acquire support and lead the firm in a creative undertaking. These observations are of some importance because they imply that the old myth that leaders do not need expertise, they just need to know how to lead, does not apply in the case of creative efforts.

Creative thinking skills, planning skills, and expertise are all distinctly cognitive capacities. Leaders of creative efforts, however, will also need substantial social skills. Social skills are needed to establish the networks used by leaders in scanning and to establish relationships with other units in the firm. Social skills are also needed to establish a viable team climate and provide people with feedback concerning the work being done. Prior studies have shown one key difference between the leaders of creative efforts and high performing creative people is that leaders demonstrate substantial social skills. In this regard, however, it should be borne in mind that the social skills needed by those asked to lead creative efforts are not simply a matter of being friendly—Leaders, at times, must provide critical feedback. Moreover, leaders of creative efforts must be skilled at appraising others, they must be able to monitor the interactions among team members, and they must be able to regulate their own, and others', emotions—arising from the various crises that emerge in the course of any creative effort.

Beyond social skills, leaders must possess one other capacity likely to prove to be an important influence on performance. Creative efforts are inherently ambiguous, and in any firm, the concerns at hand are not just the success of the creative effort, but its impact on and value to the firm. Leaders, as a result, must be aware of, and be able to balance, these pressures as they guide the development of creative products. Leaders, moreover, must be able to appraise the fit of a creative effort to both the needs of the firm and the profession, taking into account relevant risks and payoffs. As a result, it seems clear that those asked to lead creative efforts need wisdom. A study by [Connelly et al. \(2000\)](#) showed that social judgment skills linked to wisdom are strongly, and positively, related to performance in the leadership of creative efforts.

Leader Errors

The need for wisdom points to a key error often made by those asked to lead creative efforts. When people are presented with new ideas, they are evaluative, critical, and seek to identify the deficiencies evident in the idea presented. [Loneragan et al. \(2004\)](#) asked people to assume the role of a leader in a marketing firm appraising advertising programs of known quality and originality under innovative or efficiency standards. They found that the most creative products emerged when high-quality ideas were appraised with respect to innovative potential, and when highly original ideas were appraised with respect to efficiency. Thus, leaders of creative efforts must compensate for deficiencies in ideas, not just criticize the ideas produced. Indeed, harsh, non-compensatory evaluations may act to demotivate creative people and undermine the engaged, intellectual, climate needed by creative work.

Leaders of creative efforts, moreover, cannot evaluate just the idea as it stands. Leaders must be able to envision how this idea will unfold over time, both within the profession and within the firm. Put differently, leaders of creative efforts must be able to forecast downstream. Both, qualitative studies of the development radical new innovations and empirical studies of performance in leading creative efforts indicate that extensive forecasting is critical to leader performance.

Like the people doing the creative work, the leaders of creative efforts have much invested in the creative work that has been accomplished. Creative leaders “love” their creative products. This results in a tendency of leaders to try to protect the product they, and their team, produced. The problem that arises here is that as ideas move from initial development to fielding, many

changes must be made. If leaders seek to protect the integrity of the idea, at the expense of the needs imposed by fielding, performance will suffer. The errors arising from idea protection will be more likely if the leader isolates themselves, or the project team, from contact with other units of the firm or other stakeholders. Prior studies indicate that successful leaders of creative efforts take actions to minimize the negative effects of isolation on creative teams.

Lack of compensation, limited forecasting, and protection of sunk costs in ideas one has worked on are endemic sources of error in all humans. Leaders, due to the nature of leadership roles, are prone to make two distinct types of errors. One error is associated with the need for deep processing and one error is associated with the need for ongoing learning.

In firms, leaders must do many things—attend meetings, complete forms, track budgets—and, as a result, leaders lack time and are under substantial pressure. Thus, leaders often simply try to move through things and get them out of the way. This work strategy, of course, undermines depth processing—leaders often believe they can not dwell on things. Creative ideas are novel, complex ideas with many implications. As a result, failure to process ideas deeply will undermine leader performance. In fact, there is reason to believe that unless leaders think about ideas deeply, they will not ever see the potential value in a creative idea. This point is noteworthy because it implies that leaders must use work strategies, such as time blocking, that give them time to think deeply about the ideas that they are being presented with.

In firms, leaders are also under intense production pressures. Firms want success and they want creative work to be done in a cost-efficient fashion. Creative efforts, however, often fail and failure, to the leaders of creative efforts, is not necessarily a problem if the leader, the team, and the firm learn from failure. However, the pressure for production may cause leaders to lose sight of the need for ongoing learning as they pursue creative projects. By devaluing learning, the long-term success of creative efforts will suffer, resulting in errors. By the same token, these observations imply that leaders must find ways to maintain their curiosity, even as they grapple with substantial production pressures.

Conclusions

Leadership of creative efforts may be among the single most demanding forms of work any leader is asked to do. It may, in fact, be harder to be the Research and Development Director than the President of the firm. To effectively guide creative efforts, leaders must lead the work, the team, and the firm—three distinct activities which must be integrated. To execute these activities, leaders must do many things. They must constantly be scanning their environment, they must be able to plan projects, they must provide viable feedback, they must establish a creative climate, they must sell, and they must teach.

To complicate matters further, if they are to lead these efforts successfully, they have to avoid common mistakes. They cannot just evaluate, they must compensate. They have to look downstream. They have to think in depth, and continually learn, even as they cope with substantial production pressures. They must be technically skilled, experts in their field, but they must also know people, and the firm in which they're working.

These many substantial demands have a noteworthy implication. The leaders of creative efforts, at least successful leaders, don't just appear by magic. Systematic efforts, long-term, appropriately scaffolded developmental programs, must be put in place to prepare people to lead creative projects. The hope is that this entry provides an impetus for future work intended to establish exactly how to prepare people to become the leaders of creative efforts.
